preliminary draft: April 2004

## Abstract

This chapter discusses estimation, specification testing, and model selection of predictive density models. In particular, predictive density estimation is briefly discussed, and a variety of different specification and model selection tests due to various authors including Diebold, Gunther and Tay (1998), White (2000), Bai (2003), Corradi and Swanson (2003a,b,c), Hong and Li (2003) and numerous others are reviewed. Extensions to some existing techniques to the case of out-of-sample evaluation are also provided, and asymptotic results associated with these extensions are outlined.

Swanson, Department of Economics, Rutgers University, 75 Hamilton Street, New Brunswick, NJ 08901, USA, nswanson@econ.rutgers.edu. This article was prepared for the Handbook of Economic Forecasting. The authors owe great thanks to Clive W.J. Granger, whose discussions provided much of the impetus for the authors' own research that is reported in this paper. Corradi gratefully acknowledges ESRC grant RES-000-23-0006, and Swanson acknowledges financial support from a Rutgers University Research Council grant.

# Outline

## Part I: Introduction

### 1. Estimation, Specification Testing, and Model Selection

*Table 1. Summary of Selected Specification Testing and Model Selection Papers*

## Part II: Testing for Correct Specification of Conditional Distributions for the Entire or a Given Information Set

### 2. Specification Testing and Model Selection In-Sample

2.1 Diebold, Gunther and Tay Approach - Probability Integral Transform

2.2 Bai Approach - Martingalization

2.3 Hong and Li Approach - A Nonparametric Test

2.4 Corradi and Swanson Approach - A Parametric Test

2.5 Bootstrap Critical Values for the  $V_{1T}$  and  $V_{2T}$  Tests

2.6 Tests Based on Normality Transformations

2.7 Other Related Work

### 3. Specification Testing and Model Selection Out-of-Sample

3.1 Parameter Estimation Error in Recursive and Rolling Estimation Schemes - West as well as West and McCracken Results

3.2 Out-of-Sample Implementation of Bai as well as Hong and Li Tests

3.3 Out-of-Sample Implementation of Corradi and Swanson Tests

3.4 Bootstrap Critical Values for  $V_{1P,J}$  and  $V_{2P,J}$  Tests Under Recursive Estimation

3.4.1 Split Sample Recursive PEE Bootstrap

3.4.2 Full Sample Recursive PEE Bootstrap

3.4.3  $V_{1P,J}$  and  $V_{2P,J}$  Bootstrap Statistics Under Recursive Estimation

3.5 Bootstrap Critical Values for  $V_{1P,J}$  and  $V_{2P,J}$  Tests Under Rolling Estimation

3.5.1 Split Sample Rolling PEE Bootstrap

3.5.2 Full Sample Rolling PEE Bootstrap

3.5.3  $V_{1P,J}$  and  $V_{2P,J}$  Bootstrap Statistics Under Rolling Estimation

## Part III: Evaluation of (Multiple) Misspecified Predictive Models

### 4. Pointwise Comparison of (Multiple) Misspecified Predictive Models

4.1 Comparison of Two Nonnested Models: Diebold and Mariano Test

4.2 Comparison of Two Nested Models

4.2.1 Clark and McCracken Tests

4.2.2 Chao, Corradi and Swanson Tests

4.3 Comparison of Multiple Models: The Reality Check

4.3.1 White's Reality Check and Extensions

4.3.2 Hansen's Approach to the Reality Check

*4.3.3 The Subsampling Approach Applied to the Reality Check*

*4.3.4 The False Discovery Rate Approach Applied to the Reality Check*

*4.4 A Predictive Accuracy Test That is Consistent Against Generic Alternatives*

*5. Comparison of (Multiple) Misspecified Predictive Density Models*

*5.1 The Kullback-Leibler Information Criterion Approach*

*5.2 A Predictive Density Accuracy Test for Comparing Multiple Misspecified Models*

*5.2.1 A Mean Square Error Measure of Distributional Accuracy*

*5.2.2 The Test Statistic and Its Asymptotic Behavior*

*5.2.3 Bootstrap Critical Values for the Density Accuracy Test*

## Part IV: Appendix and References

# Part I: Introduction

## 1 Estimation, Specification Testing, and Model Selection

This topic of predictive density evaluation has received considerable attention in economics and finance over the last few years, a fact which is not at all surprising when one notes the importance of predictive densities to virtually all public and private institutions involved with the construction and dissemination of forecasts. As a case in point, consider the plethora conditional mean forecasts reported by the news media. These sorts of predictions are not very useful for economic decision making unless confidence intervals are also provided. For example, there is a clear need when forming macroeconomic policies and when managing financial risk in the insurance and banking industries to use predictive confidence intervals or entire predictive conditional distributions. One such case is when value at risk measures are constructed in order to assess the amount of capital at risk from small probability events, such as catastrophes (in insurance markets) or monetary shocks that have large impact on interest rates (see Duffie and Pan (1997) for further discussion). In this chapter we shall discuss various tools useful in such situations, with particular focus on estimation, specification testing, and model selection.

There are many important historical precedents for predictive density estimation, testing, and model selection. From the perspective of estimation, the parameters characterizing distributions, conditional distributions and predictive densities can be constructed using innumerable well established techniques, including maximum likelihood, (simulated generalized) methods of moments, and a plethora of other estimation techniques. Additionally, one can specify parametric models, nonparametric models, and semi-parametric models. For example, a random variable of interest, say  $y_t$ , may be assumed to have a particular distribution, say  $F(u|\theta_0) = P(y \leq u|\theta_0) = \Phi(u) = \int_{-\infty}^u f(y)dy$ , where  $f(y) = \frac{1}{\sigma\sqrt{2\pi}}e^{-\frac{(y-\mu)^2}{2\sigma^2}}$ . Here, the consistent maximum likelihood estimator of  $\theta_0$  is  $\hat{\mu} = n^{-1} \sum_{t=1}^T y_t$ , and  $\hat{\sigma}^2 = n^{-1} \sum_{t=1}^T (y_t - \hat{\mu})^2$ , where  $T$  is the sample size. This example corresponds to the case where the variable of interest is a martingale difference sequence and so there is no potentially useful (conditioning) information which may help in prediction. Then, the predictive density for  $y_t$  is simply  $\hat{f}(y) = \frac{1}{\hat{\sigma}\sqrt{2\pi}}e^{-\frac{(y-\hat{\mu})^2}{2\hat{\sigma}^2}}$ . Alternatively, one may wish to use a nonparametric estimator. For example, if the functional form of the distribution is unknown, one might choose to construct a kernel density estimator. In this case, one would construct  $\hat{f}(y) = \frac{1}{T\lambda} \sum_{t=1}^T \kappa\left(\frac{y_t - y}{\lambda}\right)$ , where  $\kappa$  is a kernel function and  $\lambda$  is the bandwidth parameter that satisfies a particular rate condition in order to ensure consistent estimation, such as  $\lambda = O(T^{-1/5})$ . Nonparametric approaches to estimation such as this

are quite prevalent and indeed we shall see later that some of the most important tools in testing and model selection rely on the empirical distribution (see e.g. Andrews (1993) for a thorough overview of empirical distributions, and empirical processes in general). In particular, the empirical distribution is crucial in our discussion of predictive density because it is useful in estimation, testing, and model selection, and has the property that

$$\frac{1}{T} \sum_{i=1}^T \mathbf{1}\{y_t \leq u\} \xrightarrow{pr} F(u|\theta_0), \quad \text{for } u \in U.$$

Of course, in economics it is natural to suppose that better predictions can be constructed by conditioning on other important economic variables, say. Indeed, discussions of predictive density are usually linked to discussions of conditional distribution, where we define conditioning information as  $Z^t = (y_{t-1}, \dots, y_{t-v}, X_t, \dots, X_{t-w})$  with  $v, w$  finite, and where  $X_t$  may be vector valued. In this context, we could define a model corresponding to the above conditional distribution as

$$F(u|Z^t, \theta_0) = \Pr(Y_t \leq u|Z^t).$$

Alternatively, one may wish to estimate and evaluate a group of alternative models, say  $F_1(u|Z^t, \theta_1^\dagger), \dots, F_m(u|Z^t, \theta_m^\dagger)$ , where the parameters in these distributions correspond to the probability limits of the estimated parameters, and  $m$  is the number of models to be estimated and evaluated. Estimation in this context can be carried out in much the same way as when unconditional models are estimated. A leading example is the case where one specifies a conditional mean model, say as  $u_t = E(y_t|Z^t, \theta_0) = a + \sum_i b_i y_{t-i} + \sum_j c_{1j} X_{1,t-j} + \dots + \sum_j c_{wj} X_{w,t-j}$ , and further assumes that  $u_t \sim iidN(0, \sigma^2)$ , so that the conditional distribution and corresponding predictive density can be estimated by first forming estimates of  $\theta_0$  using least squares. Residuals, say  $\hat{u}_t = E(y_t|Z^t, \theta_0) - \hat{E}(y_t|Z^t, \theta_0)$ , are then used to estimate the variance parameter of the normal density describing  $u_t$ , just as in our first example. The foregoing discussion underscores the fact that there are numerous well established estimation techniques which one can use to estimate predictive density models, and hence which one can use to make associated probabilistic statements such as: "There is 0.9 probability, based on the use of my particular model, that inflation next period will lie between 4 and 5 percent." Indeed, for a discussion of estimation, one need merely pick up any basic or advanced statistics and/or econometrics text. Naturally, and as one might expect, the appropriateness of a particular estimation technique hinges on two factors. The first is the nature of the data. Marketing survey data are quite different from aggregate measures of economic activity, and there are well established literatures describing appropriate models and estimation techniques for these and other varieties of data, from spatial to panel, and from time series to cross sectional. Given that there is already a huge literature on the topic of estimation, we shall hereafter

assume that the reader has at her/his disposal software and knowhow concerning model estimation (for some discussion of estimation in cross sectional, panel, and time series models, for example, the reader might refer to Baltagi (1995), Bickel and Doksum (2001), Davidson and McKinnon (1993), Hamilton (1996), White (1994), and Wooldridge (2002), to name but a very few). The second factor upon which the appropriateness of a particular estimation strategy hinges concerns model specification. In the context of model specification and selection, it is crucial to make it clear in empirical settings whether one is assuming that a model is correctly specified (prior to estimation), or whether the model is simply an approximation, possibly from amongst a group of many “approximate models”, from whence some “best” predictive density model is to be selected. The reason this assumption is important is because it impacts on the assumed properties of the residuals from the first stage conditional mean regression in the above example, which in turn impacts on the validity and appropriateness of specification testing and model selection techniques that are usually applied after a model has been estimated.

The focus in this chapter is on the last two issues, namely specification testing and model selection. One reason why we are able to discuss both of these topics in a (relatively) short handbook chapter is that the literature on the subjects is not near so large as that for estimation; although it is currently growing at an impressive rate! The fact that the literature in these areas is still relatively underdeveloped is perhaps surprising, given that the “tools” used in specification testing and model selection have been around for so long, and include such important classical contributions as the Kolmogorov-Smirnov test (see e.g. Kolmogorov (1933) and Smirnov (1939)), various results on empirical processes (see e.g. Andrews (1993) and the discussion in chapter 19 of van der Vaart (1998) on the contributions of Glivenko, Cantelli, Doob, Donsker and others), the probability integral transform (see e.g. Rosenblatt (1952)), and the Kullback-Leibler Information Criterion (see e.g. White (1982) and Vuong (1989)). However, the immaturity of the literature is perhaps not so surprising when one considers that many of the contributions in the area depend upon recent advances including results validating the use of the bootstrap (see e.g. Horowitz (2001)) and the invention of crucial tools for dealing with parameter estimation error (see e.g. Khmaladze (1981,1988) and West (1996)), for example.

In order to carry out a systematic discussion of specification testing and model selection, we start by outlining various contributions which are from the literature on (consistent) specification testing (see e.g. Bierens (1982,1990) and Bierens and Ploberger (1997)). An important feature of such tests is that if one subsequently carries out a series of these tests, such as when one performs a series of specification tests using alternative conditional distributions (e.g. the conditional Kolmogorov-Smirnov test of Andrews (1997)),

then sequential test bias arises (i.e. critical values may be incorrectly sized, and so inference based on such sequential tests may be incorrect). Additionally, it may be difficult in some contexts to justify the assumption under the null that a model is correctly specified, as we may want to allow for possible dynamic misspecification under the null, for example. After all, if two tests for the correct specification of two different models are carried out sequentially, then surely one of the models is misspecified under the null, implying that the critical values of one of the two tests may be incorrect, as we shall shortly illustrate. It is in this sense that the idea of model selection in which a group of models are jointly compared, and in which case all models are allowed to be misspecified, is important, particularly from the perspective of prediction. After all, there are many settings for which the objective is not to find the correct model, but rather to select the “best” model (based on a given metric or loss function to be used for predictive evaluation) from amongst a group of models, all of which are approximations to some underlying unknown model. Nevertheless, given that advances in multiple model comparison under misspecification derive to a large extent from earlier advances in (correct) specification testing, and given that specification testing and model selection are likely most powerful when used together, we shall discuss tools and techniques in both areas.

Although a more mature literature, there is still a great amount of activity in the area of tests for the correct specification of conditional distributions. One reason for this is that testing for the correct conditional distribution is equivalent to jointly evaluating many conditional features of a process, including the conditional mean, variance, and symmetry. Along these lines, Inoue (1999) constructs tests for generic conditional aspects of a distribution, and Bai and Ng (2001) construct tests for conditional asymmetry. These sorts of tests can be generalized to the evaluation of predictive intervals and predictive densities, too.

One group of tests that we discuss along these lines is that due to Corradi and Swanson (2003a). In their paper, they construct Kolmogorov type conditional distribution tests in the presence of both dynamic misspecification and parameter estimation error. As shall be discussed shortly, the approach taken by these authors differs somewhat from much of the related literature because they construct a statistics that allow for dynamic misspecification under both hypotheses, rather than assuming correct dynamic specification under the null hypothesis. This difference can be most easily motivated within the framework used by Diebold, Gunther and Tay (DGT: 1998), Hong (2001), and Bai (2003). In their paper, DGT use the probability integral transform to show that  $F_t(y_t|\mathfrak{S}_{t-1}, \theta_0)$  is identically and independently distributed as a uniform random variable on  $[0, 1]$ , where  $F_t(\cdot|\mathfrak{S}_{t-1}, \theta_0)$  is a parametric distribution with underlying parameter  $\theta_0$ ,  $y_t$  is again our random variable of interest, and  $\mathfrak{S}_{t-1}$  is the information set containing all “relevant” past information (see below for further discussion). They thus suggest using the difference between the empirical distribution

of  $F_t(y_t|\mathfrak{I}_{t-1}, \hat{\theta}_T)$  and the  $45^\circ$ –degree line as a measure of “goodness of fit”, where  $\hat{\theta}_T$  is some estimator of  $\theta_0$ . This approach has been shown to be very useful for financial risk management (see e.g. Diebold, Hahn and Tay (1999)), as well as for macroeconomic forecasting (see e.g. Diebold, Tay and Wallis (1998) and Clements and Smith (2000,2002)). Likewise, Bai (2003) proposes a Kolmogorov type test of  $F_t(u|\mathfrak{I}_{t-1}, \theta_0)$  based on the comparison of  $F_t(y_t|\mathfrak{I}_{t-1}, \hat{\theta}_T)$  with the CDF of a uniform on  $[0, 1]$ . As a consequence of using estimated parameters, the limiting distribution of his test reflects the contribution of parameter estimation error and is not nuisance parameter free. To overcome this problem, Bai (2003) uses a novel approach based on a martingalization argument to construct a modified Kolmogorov test which has a nuisance parameter free limiting distribution. This test has power against violations of uniformity but not against violations of independence (see below for further discussion). Hong (2001) proposes another related interesting test, based on the generalized spectrum, which has power against both uniformity and independence violations, for the case in which the contribution of parameter estimation error vanishes asymptotically. If the null is rejected, Hong (2001) also proposes a test for uniformity robust to non independence, which is based on the comparison between a kernel density estimator and the uniform density. All of these tests are discussed in detail below. In summary, two features differentiate the tests of Corradi and Swanson (CS: 2003a) from the tests outlined in the other papers mentioned above. First, CS assume strict stationarity. Second, CS allow for dynamic misspecification under the null hypothesis. The second feature allows CS to obtain asymptotically valid critical values even when the conditioning information set does not contain all of the relevant past history. More precisely, assume that we are interested in testing for correct specification, given a particular information set which may or may not contain all of the relevant past information. This is relevant when a Kolmogorov test is constructed, as one is generally faced with the problem of defining  $\mathfrak{I}_{t-1}$ . If enough history is not included, then there may be dynamic misspecification. Additionally, finding out how much information (e.g. how many lags) to include may involve pre-testing, hence leading to a form of sequential test bias. By allowing for dynamic misspecification, such pre-testing is not required.

To be more precise, critical values derived under correct specification given  $\mathfrak{I}_{t-1}$  are not in general valid in the case of correct specification given a subset of  $\mathfrak{I}_{t-1}$ . Consider the following example. Assume that we are interested in testing whether the conditional distribution of  $y_t|y_{t-1}$  is  $N(\alpha_1^\dagger y_{t-1}, \sigma_1)$ . Suppose also that in actual fact the “relevant” information set has  $\mathfrak{I}_{t-1}$  including both  $y_{t-1}$  and  $y_{t-2}$ , so that the true conditional model is  $y_t|\mathfrak{I}_{t-1} = y_t|y_{t-1}, y_{t-2} = N(\alpha_1 y_{t-1} + \alpha_2 y_{t-2}, \sigma_2)$ , where  $\alpha_1^\dagger$  differs from  $\alpha_1$ . In this case, correct specification holds with respect to the information contained in  $y_{t-1}$ ; but there is dynamic misspecification with respect to  $y_{t-1}, y_{t-2}$ . Even without taking account of parameter estimation error, the

critical values obtained assuming correct dynamic specification are invalid, thus leading to invalid inference. Stated differently, tests that are designed to have power against both uniformity and independence violations (i.e. tests that assume correct dynamic specification under  $H_0$ ) will reject; an inference which is incorrect, at least in the sense that the “normality” assumption is *not* false. In summary, if one is interested in the particular problem of testing for correct specification for a given information set, then the CS approach is appropriate, while if one is instead interested in testing for correct specification assuming that  $\mathfrak{S}_{t-1}$  is known, that the other tests discussed above are useful - these are some of the tests discussed in the second part of this chapter, and all are based on probability integral transforms and Kolmogorov Smirnov distance measures.

In the third part of this chapter, attention is turned to the case of model selection. Much of the development in this area stems from earlier work in the area of point evaluation, and hence various tests of conditional mean models for nested and nonnested models, both under assumption of correct specification, and under the assumption that all models should be viewed as “approximations”, are first discussed. These tests include important ones by Diebold and Mariano (1995), West (1996), White (2000), and many others. Attention is then turned to a discussion of predictive density selection. To illustrate the sort of model selection tools that are discussed, consider the following. Assume that we are given a group of (possibly) misspecified conditional distributions,  $F_1(u|Z^t, \theta_1^\dagger), \dots, F_m(u|Z^t, \theta_m^\dagger)$ , and assume that the objective is to compare these models in terms of their “closeness” to the true conditional distribution,  $F_0(u|Z^t, \theta_0) = \Pr(Y_{t+1} \leq u|Z^t)$ . Corradi and Swanson (2003b,c) consider such a problem. If  $m > 2$ , they follow White (2000), in the sense that a particular conditional distribution model is chosen as the “benchmark” and one tests the null hypothesis that no competing model can provide a more accurate approximation of the “true” conditional distribution against the alternative that at least one competitor outperforms the benchmark model. However, unlike White, they evaluate predictive densities rather than point forecasts. Pairwise comparison of alternative models, in which no benchmark needs to be specified, follows from their results as a special case. In their context, accuracy is measured using a distributional analog of mean square error. More precisely, the squared (approximation) error associated with model  $i$ ,  $i = 1, \dots, m$ , is measured in terms of  $E \left( \left( F_i(u|Z^{t+1}, \theta_i^\dagger) - F_0(u|Z^{t+1}, \theta_0) \right)^2 \right)$ , where  $u \in U$ , and  $U$  is a possibly unbounded set on the real line.

Another well known measure of distributional accuracy which is also discussed in Part 3 is the Kullback-Leibler Information Criterion (KLIC). The KLIC is useful because the “most accurate” model can shown to be that which minimizes the KLIC (see below for more details). Using the KLIC approach, Giacomini (2002) suggests a weighted version of the Vuong (1989) likelihood ratio test for the case of dependent observations,

while Kitamura (2002) employs a KLIC based approach to select among misspecified conditional models that satisfy given moment conditions. Furthermore, the KLIC approach has been recently employed for the evaluation of dynamic stochastic general equilibrium models (see e.g. Schörfheide (2000), Fernandez-Villaverde and Rubio-Ramirez (2004), and Chang, Gomes and Schörfheide (2002)). For example, Fernandez-Villaverde and Rubio-Ramirez (2004) show that the KLIC-best model is also the model with the highest posterior probability. In general, there is no reason why either of the above two measures of accuracy is more “natural”. These tests are discussed in detail in the chapter.

As a further preamble to this chapter, we now present a table which summarizes selected testing and models selection papers. The list of papers in the table is undoubtedly incomplete, but nevertheless serves as a rough benchmark to the sorts of papers and results that are discussed in this chapter. The primary reason for including the table is to summarize in a directly comparable manner the assumptions made in the various papers. Later on, assumptions are given as they appear in the original papers.

Table 1: Summary of Selected Specification Testing and Model Selection Papers

| Paper                                        | Eval | Test | Misspec | Loss | PEE | Horizon    | Nesting | CV            |
|----------------------------------------------|------|------|---------|------|-----|------------|---------|---------------|
| Diebold, Gunther and Tay (1998) <sup>1</sup> | S    | CD   | C       | NA   | No  | $h = 1$    | NA      | NA            |
| Bai (2003) <sup>2</sup>                      | S    | CD   | C       | NA   | Yes | $h = 1$    | NA      | Standard      |
| Corradi and Swanson (2003a) <sup>1</sup>     | S    | CD   | D       | NA   | Yes | $h = 1$    | NA      | Boot          |
| Hong (2001)                                  | S    | CD   | C,D,G   | NA   | No  | $h = 1$    | NA      | Standard      |

| Thompson (2002)                              | S    | CD   | C       | NA   | Yes | $h \geq 1$ | NA      | Standard      |
| West (1996)                                  | P    | CM   | C       | D    | Yes | $h \geq 1$ | O       | Standard      |
| White (2000) <sup>4</sup>                    | M    | CM   | G       | N    | Yes | $h \geq 1$ | O       | Boot          |

Notes: The table provides a summary of various tests currently available. For completeness, some tests of conditional mean are also included, particularly when they have been, or could be, extended to the case of conditional distribution evaluation. Many tests are considered ancillary, or have been omitted due to ignorance. Many other tests are discussed in the papers cited in this table. “NA” entries denote “Not Applicable”. Columns and mnemonics used are defined as follows:

\* *Eval* = Evaluation is of: Single Model (S); Pair of Models (P); Multiple Models (M).

\* *Test* = Test is of: Conditional Distribution (CD); Conditional Mean (CM).

\* *Misspec* = Misspecification assumption under  $H_0$ : Correct Specification (C); Dynamic Misspecification Allowed (D); General Misspecification Allowed (G).

\* *Loss* = Loss function assumption: Differentiable (D); May be Non-differentiable (N).

\* *PEE* = Parameter estimation error: Accounted for (yes); Not Accounted for (no).

\* *Horizon* = Prediction horizon: 1-step ( $h = 1$ ); Multi-step ( $h \geq 1$ ).

\* *Nesting* = Assumption vis nestedness of models: (At least one) Nonnested Model Required (O); Nested Models (N); Any Combination (A).

\* *CV* = Critical values constructed via: Standard Limiting Distribution or Nuisance Parameter Free Nonstandard Distribution (Standard); Bootstrap or Other Procedure (Boot).

<sup>1</sup> Extension to multiple horizon follows straightforwardly if the marginal distribution of the errors is normal, for example; otherwise extension is not always straightforward.

<sup>2</sup> See extension in this paper to out-of-sample case.

<sup>3</sup> This is the only predictive accuracy test from the listed papers that is consistent against generic (nonlinear) alternatives.

<sup>4</sup> See extension in this paper to predictive density evaluation, allowing for parameter estimation error.

<sup>5</sup> Parameters are estimated using a fixed window of observations, so that parameters do not approach their probability limits, but are instead treated as mixing variables under the null hypothesis.

# Part II: Testing for Correct Specification of Conditional Distributions for the Entire or a Given Information Set

## 2 Specification Testing and Model Selection In-Sample

EXTEND .....

### 2.1 Diebold, Gunther and Tay Approach - Probability Integral Transform

In a key paper in the field, Diebold, Gunther and Tay (DGT: 1998) use the probability integral transform (see e.g. Rosenblatt (1952)) to show that  $F_t(y_t|Z^{t-1}, \theta_0) = \int_{-\infty}^{y_t} f_t(y|Z^{t-1}, \theta_0) dy$ , is identically and independently distributed as a uniform random variable on  $[0, 1]$ . They thus suggest using the difference between the empirical distribution of  $F_t(y_t|Z^{t-1}, \hat{\theta}_T)$  and the  $45^\circ$ -degree line as a measure of “goodness of fit”, where  $\hat{\theta}_T$  is some estimator of  $\theta_0$ . This approach has been shown to be very useful for financial risk management (see e.g. Diebold, Hahn and Tay (1998)), as well as for macroeconomic forecasting (see e.g. Diebold, Tay and Wallis (1998) and Clements and Smith (2000,2002)). Formal tests based on the DGT probability integral transformation approach which take into account the issue of parameter estimation error have recently been provided by Bai (2003), Hong (2001) and Corradi and Swanson (2003a).

EXTEND .....

### 2.2 Bai Approach - Martingalization

Bai (2003) considers the following hypotheses:

$$H_0 : \Pr(y_t \leq y|\mathfrak{S}_{t-1}, \theta_0) = F_t(y|\mathfrak{S}_{t-1}, \theta_0), \text{ a.s. for some } \theta_0 \in \Theta \quad (1)$$

$$H_A : \text{the negation of } H_0, \quad (2)$$

where  $\mathfrak{S}_{t-1}$  contains all the relevant history up to time  $t - 1$ . In this sense, the null hypotheses corresponds with dynamic correct specification of the conditional distribution.

Bai (2003) proposes a Kolmogorov type test based on the comparison of  $F_t(y|\mathfrak{S}_{t-1}, \theta_0)$  with the CDF of a uniform random variable on  $[0, 1]$ . In practice, we need to replace the unknown parameters,  $\theta_0$ , with

an estimator, say  $\hat{\theta}_T$ . Additionally, we often do not observe the full information set  $\mathfrak{I}_{t-1}$ , but only a subset of it, say  $Z^t \subseteq \mathfrak{I}_{t-1}$ . Therefore, we need to approximate  $F_t(y|\mathfrak{I}_{t-1}, \theta_0)$  with  $F_t(y|Z^{t-1}, \hat{\theta}_T)$ . Hereafter, for notational simplicity, define

$$\hat{U}_t = F_t(y_t|Z^{t-1}, \hat{\theta}_T) \quad (3)$$

$$\tilde{U}_t = F_t(y_t|Z^{t-1}, \theta^\dagger) \quad (4)$$

$$U_t = F_t(y_t|\mathfrak{I}_{t-1}, \theta_0), \quad (5)$$

where  $\theta^\dagger = \theta_0$  whenever  $Z^{t-1}$  contains all useful information in  $\mathfrak{I}_{t-1}$ , so that in this case  $\tilde{U}_t = U_t$ . As a consequence of using estimated parameters, the limiting distribution of his test reflects the contribution of parameter estimation error and is not nuisance parameter free. In fact, as shown in his eqs.(1)-(4),

$$\begin{aligned} \hat{V}_T(r) &= \frac{1}{\sqrt{T}} \sum_{t=1}^T \left( 1\{\hat{U}_t \leq r\} - r \right) \\ &= \frac{1}{\sqrt{T}} \sum_{t=1}^T \left( 1\{\tilde{U}_t \leq r\} - r \right) + \bar{g}(r)' \sqrt{T} (\hat{\theta}_T - \theta^\dagger) + o_P(1), \\ &= \frac{1}{\sqrt{T}} \sum_{t=1}^T (1\{U_t \leq r\} - r) + \bar{g}(r)' \sqrt{T} (\hat{\theta}_T - \theta_0) + o_P(1) \end{aligned} \quad (6)$$

where the last equality holds only if  $Z^{t-1}$  contains all useful information in  $\mathfrak{I}_{t-1}$ . Here,

$$\bar{g}(r) = \text{plim}_{T \rightarrow \infty} \frac{1}{T} \sum_{t=1}^T \frac{\partial F_t}{\partial \theta}(x|Z^{t-1}, \theta^\dagger)|_{x=F_t^{-1}(r|Z^{t-1}, \theta^\dagger)}.$$

Also, let

$$g(r) = (1, \bar{g}(r)').$$

To overcome the nuisance parameter problem, Bai uses a novel approach based on a martingalization argument to construct a modified Kolmogorov test which has a nuisance parameter free limiting distribution. In particular, let  $\dot{g}$  be the derivative of  $g$ , and let  $C(r) = \int_r^1 \dot{g}(\tau) \dot{g}(\tau)' d\tau$ . Bai's test statistic (eq.(5), p. 533) is defined as:

$$\widehat{W}_T(r) = \widehat{V}_T(r) - \int_0^r \left( \dot{g}(s) C^{-1}(s) \dot{g}(s)' \int_s^1 \dot{g}(\tau) d\widehat{V}_T(\tau) \right) ds, \quad (7)$$

where the second term may be difficult to compute, depending on the specific application. Several examples, including GARCH models and (self-exciting) threshold autoregressive models are provided in Section IIIB

of Bai (2003). The limiting distribution of the statistic in (7) is obtained under the following assumptions, where it is of note that stationarity is not required. (Note also that **BAI4** below rules out non-negligible differences between the information in  $Z^{t-1}$  and  $\mathfrak{S}_{t-1}$ , with respect to the model of interest).

**BAI1:**  $F_t(y_t|Z^{t-1}, \theta)$  and its density  $f_t(y_t|Z^{t-1}, \theta)$  are continuously differentiable in  $\theta$ .  $F_t(y|Z^{t-1}, \theta)$  is strictly increasing in  $y$ , so that  $F_t^{-1}$  is well defined. Also,

$$E \sup_x \sup_\theta f_t(y_t|Z^{t-1}, \theta) \leq M_1 < \infty$$

and

$$E \sup_x \sup_\theta \left\| \frac{\partial F_t}{\partial \theta}(x|Z^{t-1}, \theta) \right\| \leq M_1 < \infty,$$

where the supremum is taken over all  $\theta$ , such that  $|\theta - \theta^\dagger| \leq MT^{-1/2}$ ,  $M < \infty$ .

**BAI2:** There exists a continuously differentiable function  $\bar{g}(r)$ , such that for every  $M > 0$ ,

$$\sup_{\substack{u,v \\ |u-\theta^\dagger| \leq MT^{-1/2}, |v-\theta^\dagger| \leq MT^{-1/2}}} \left\| \frac{1}{T} \sum_{t=1}^T \frac{\partial F_t}{\partial \theta}(F_t^{-1}(r|u)|v) - \bar{g}(r) \right\| = o_P(1),$$

where the  $o_P(1)$  is uniform in  $r \in [0, 1]$ . In addition,  $\int_0^1 \|\dot{g}(r)\| dr < \infty$ ,  $C(r) = \int_r^1 \dot{g}(\tau) \dot{g}(\tau)' d\tau$  is invertible for all  $r$ .

**BAI3:**  $\hat{\theta}_T$  satisfies  $\sqrt{T}(\hat{\theta}_T - \theta^\dagger) = O_P(1)$ .

**BAI4:** The effect of using  $Z^{t-1}$  instead of  $\mathfrak{S}_{t-1}$  is negligible. That is,

$$\sup_{u, |u-\theta_0| \leq MT^{-1/2}} T^{-1/2} \sum_{t=1}^T |F_t(F_t^{-1}(r|Z^{t-1}, u)|\mathfrak{S}_{t-1}, \theta_0) - F_t(F_t^{-1}(r|\mathfrak{S}_{t-1}, u)|\mathfrak{S}_{t-1}, \theta_0)| = o_P(1)$$

Given this setup, the following result can be proven.

**Theorem 2.1 (from Corollary 1 in Bai (2003)):** Let **BAI1-BAI4** hold, then under  $H_0$ ,

$$\sup_{r \in [0, 1]} \widehat{W}_T(r) \xrightarrow{d} \sup_{r \in [0, 1]} W(r),$$

where  $W(r)$  is a standard Brownian motion. Therefore, the limiting distribution is nuisance parameter free and critical values can be tabulated.

Now, suppose there is dynamic misspecification, so that  $\Pr(y_t \leq y|\mathfrak{S}_{t-1}, \theta_0) \neq \Pr(y_t \leq y|Z^{t-1}, \theta^\dagger)$ . In this case, critical values relying on the limiting distribution in Theorem 1.1 are no longer valid. However, if  $F(y_t|Z^{t-1}, \theta^\dagger)$  is correctly specified for  $\Pr(y_t \leq y|Z^{t-1}, \theta^\dagger)$ , uniformity still holds, and there is no guarantee that the statistic diverges. Thus, while Bai's test has unit asymptotic power against violations of uniformity, it does not have unit asymptotic power against violations of independence. Note that in the case of dynamic

misspecification, assumption **BAI4** is violated. Also, the assumption cannot be checked from the data, in general. In summary, the limiting distribution of Kolmogorov type tests is affected by dynamic misspecification. Critical values derived under correct dynamic specification are not in general valid in the case of correct specification given a subset of the full information set. Consider the following example. Assume that we are interested in testing whether the conditional distribution of  $y_t|y_{t-1}$  is  $N(\alpha_1^\dagger y_{t-1}, \sigma_1)$ . Suppose also that in actual fact the “relevant” information set has  $Z^{t-1}$  including both  $y_{t-1}$  and  $y_{t-2}$ , so that the true conditional model is  $y_t|Z^{t-1} = y_t|y_{t-1}, y_{t-2} = N(\alpha_1 y_{t-1} + \alpha_2 y_{t-2}, \sigma_2)$ , where  $\alpha_1^\dagger$  differs from  $\alpha_1$ . In this case, we have correct specification with respect to the information contained in  $y_{t-1}$ ; but we have dynamic misspecification with respect to  $y_{t-1}, y_{t-2}$ . Even without taking account of parameter estimation error, the critical values obtained assuming correct dynamic specification are invalid, thus leading to invalid inference.

### 2.3 Hong and Li Approach - A Nonparametric Test

As mentioned above, the Kolmogorov test of Bai does not necessarily have power against violations of independence. A test with power against violations of both independence and uniformity has been recently suggested by Hong and Li (2003). Their test is based on the comparison of the joint nonparametric density of  $\widehat{U}_t$  and  $\widehat{U}_{t-j}$ , as defined in (6), with the product of two  $UN[0, 1]$  random variables. In particular, they introduce a boundary modified kernel which ensures a “good” nonparametric estimator, even around 0 and 1. This forms the basis for a test which has power against both non-uniformity and non-independence. For any  $j > 0$ , define

$$\widehat{\phi}(u_1, u_2) = (n-j)^{-1} \sum_{\tau=j+1}^n K_h(u_1, \widehat{U}_\tau) K_h(u_2, \widehat{U}_{\tau-j}), \quad (8)$$

where

$$K_h(x, y) = \begin{cases} h^{-1}(\frac{x-y}{h}) / \int_{-(x/h)}^1 k(u) du & \text{if } x \in [0, h) \\ h^{-1}(\frac{x-y}{h}) & \text{if } x \in [h, 1-h) \\ h^{-1}(\frac{x-y}{h}) / \int_{-1}^{(1-x)/h} k(u) du & \text{if } x \in [0, h) \end{cases} \quad (9)$$

In the above expression,  $h$  defines the bandwidth parameter, although in later sections (where confusion cannot easily arise),  $h$  is used to denote forecast horizon. As an example, one might use,

$$k(u) = \frac{15}{16}(1-u^2)^2 \mathbf{1}\{|u| \leq 1\}.$$

Also, define

$$\widehat{M}(j) = \int_0^1 \int_0^1 (\widehat{\phi}(u_1, u_2) - 1)^2 du_1 du_2 \quad (10)$$

and

$$\widehat{Q}(j) = \left( (n-j)\widehat{M}(j) - A_h^0 \right) / V_0^{1/2}, \quad (11)$$

with

$$A_h^0 = \left( (h^{-1} - 2) \int_{-1}^1 k^2(u) du + 2 \int_0^1 \int_{-1}^b k_b(u) du db \right)^2 - 1,$$

$$k_b(\cdot) = k(\cdot) / \int_{-1}^b k(v) dv,$$

and

$$V_0 = 2 \left( \int_{-1}^1 \left( \int_{-1}^1 k(u+v) k(v) dv \right)^2 du \right)^2.$$

The limiting distribution of  $\widehat{Q}(j)$  is obtained by Hong and Li (2003) under the following assumptions:<sup>1</sup>

**HL1:**  $(y_t, Z^{t-1})$  are strong mixing with mixing coefficients  $\alpha(\tau)$  satisfying  $\sum_{\tau=0}^{\infty} \alpha(\tau)^{(v-1)\cdot v} \leq C < \infty$ , with  $v > 1$ .

**HL2:**  $f_t(y|Z^t, \theta)$  is twice continuously differentiable in  $\theta$ , in a neighborhood of  $\theta_0$ , and  $\lim_{T \rightarrow \infty} \sum_{\tau=1}^n E \left| \frac{\partial U_t}{\partial \theta} \right|^4 \leq C$ ,  $\lim_{T \rightarrow \infty} \sum_{\tau=1}^n E \sup_{\theta \in \Theta} \left| \frac{\partial^2 U_t}{\partial \theta \partial \theta'} \right|^2 \leq C$ , for some constant  $C$ .

**HL3:**  $\sqrt{T}(\widehat{\theta}_T - \theta^\dagger) = O_P(1)$ , where  $\theta^\dagger$  is the probability limit of  $\widehat{\theta}_T$ , and is equal to  $\theta_0$ , under the null in (1).

**HL4:** The kernel function  $k : [-1, 1] \rightarrow \mathbb{R}^+$  is a symmetric, bounded, twice continuously differentiable probability density, such that  $\int_{-1}^1 k(u) du = 0$  and  $\int_{-1}^1 k^2(u) du < \infty$ .

Given this setup, the following result can be proven.

**Theorem 2.2 (from Theorem 1 in Hong and Li (2003):** Let **HL1-HL4** hold. If  $h = cT^{-\delta}$ ,  $\delta \in (0, 1/5)$ , then under  $H_0$  (i.e. see (1)), for any  $j > 0$ ,  $j = o(T^{1-\delta(5-2/v)})$ ,  $\widehat{Q}(j) \xrightarrow{d} N(0, 1)$ .

Once the null rejected, it remains of interest to know whether the rejection is due to violation of uniformity or to violation of independence (or both). Broadly speaking, violations of independence arises in the case of dynamic misspecification ( $Z^t$  does not contain enough information), while violations of uniformity arise when we misspecify the functional form of  $f_t$  when constructing  $\widehat{U}_t$ . Along these lines, Hong (2001) proposes a test for uniformity, which is robust to dynamic misspecification. Define, the hypotheses of interest as:

$$H_0 : \Pr(y_t \leq y | Z^{t-1}, \theta^\dagger) = F_t(y | Z^{t-1}, \theta^\dagger), \text{ a.s. for some } \theta_0 \in \Theta \quad (12)$$

$$H_A : \text{the negation of } H_0, \quad (13)$$

---

<sup>1</sup>Hong et al. specialize their test to the case of testing continuous time models. However, as they point out, it is equally valid for discrete time models.

where  $F_t(y|Z^{t-1}, \theta^\dagger)$  may differ from  $F_t(y|\mathfrak{S}_{t-1}, \theta_0)$ . The relevant test is based on the comparison of a kernel estimator of the marginal density of  $\widehat{U}_t$  with the uniform density, and has a standard normal limiting distribution under the null in (12). Hong (2001) also provides a test for the null of independence, which is robust to violations of uniformity.

Note that the limiting distribution in Theorem 2.2, as well as the limiting distribution of the uniformity (independence) test which is robust to non uniformity (non independence) in Hong (2001) are all asymptotically standard normal, regardless of the fact that we construct the statistic using  $\widehat{U}_t$  instead on  $U_t$ . This is due to the feature that parameter estimators converge at rate  $T^{1/2}$ , while the statistics converge at non-parametric rates. The choice of the bandwidth parameter and the slower rate of convergence are thus the prices to be paid for not having to directly account for parameter estimation error.

## 2.4 Corradi and Swanson Approach - A Parametric Test

Corradi and Swanson (2003a) suggest a test for the null hypothesis of correct specification of the conditional distribution, for a given information set which is, as usual, called  $Z^t$ , and which, as above, does not necessarily contain all relevant historical information. The test is again a Kolmogorov type test, and is based on the fact that under the null of correct (but not necessarily dynamically correct) specification of the conditional distribution,  $U_t$  is distributed as  $[0, 1]$ . As with Hong's (2001) test, this test is thus robust to violations of independence. As will become clear below, the advantages of the test relative to that of Hong (2001) is that it converges at a parametric rate and there is no need to choose the bandwidth parameter. The disadvantage is that the limiting distribution is not nuisance parameters free and hence one needs to rely on bootstrap techniques in order to obtain valid critical values. Define:

$$V_{1T} = \sup_{r \in [0, 1]} |V_{1T}(r)|, \quad (14)$$

where,

$$V_{1T}(r) = \frac{1}{\sqrt{T}} \sum_{t=1}^T \left( 1\{\widehat{U}_t \leq r\} - r \right),$$

and

$$\widehat{\theta}_T = \arg \max_{\theta \in \Theta} \frac{1}{T} \sum_{t=1}^T \ln f(y_t|X_t, \theta).$$

Note that the above statistic is similar to that of Bai (2003). However, there is no “extra” term to cancel out the effect of parameter estimation error. The reason is that Bai’s martingale transformation argument does not apply to the case in which the score is not a martingale difference process (so that (dynamic) misspecification is not allowed for when using his test).

The standard rationale underlying the above test, which is known to hold when  $Z^{t-1} = \mathfrak{S}_{t-1}$ , is that under  $H_0$  (given above as (12)),  $F(y_t|Z^{t-1}, \theta_0)$  is distributed independently and uniformly on  $[0, 1]$ . The uniformity result also holds under dynamic misspecification. To see this, let  $c_f^r(Z^{t-1})$  be the  $r - th$  critical value of  $f(\cdot|Z^{t-1}, \theta_0)$ , where  $f$  is the density associated with  $F(\cdot|Z^{t-1}, \theta_0)$  (i.e. the conditional distribution under the null)<sup>2</sup>. It then follows that,

$$\begin{aligned}\Pr(F(y_t|Z^{t-1}, \theta_0) \leq r) &= \Pr\left(\int_{-\infty}^{y_t} f(y|Z^{t-1}, \theta_0) dy \leq r\right) \\ &= \Pr(1\{y_t \leq c_f^r(Z^{t-1})\} = 1|Z^{t-1}) = r, \text{ for all } r \in [0, 1],\end{aligned}$$

if  $y_t|Z^{t-1}$  has density  $f(\cdot|Z^{t-1}, \theta_0)$ . Now, if the density of  $y_t|Z^{t-1}$  is different from  $f(\cdot|Z^{t-1}, \theta_0)$ , then,

$$\Pr(1\{y_t \leq c_f^r(Z^{t-1})\} = 1|X_t) \neq r,$$

for some  $r$  with nonzero Lebesgue measure on  $[0, 1]$ . However, under dynamic misspecification,  $F(y_t|X_t, \theta_0)$  is no longer independent (or even martingale difference), in general, and this will clearly affect the covariance structure of the limiting distribution of the statistic. Theorem 2.3 below relies on the following assumptions.

**CS1:**  $(y_t, Z^{t-1})$ , are jointly strictly stationary and strong mixing with size  $-4(4 + \psi)/\psi$ ,  $0 < \psi < 1/2$ .

**CS2:** (i)  $F(y_t|Z^{t-1}, \theta)$  is twice continuously differentiable on the interior of  $\Theta \subset R^p$ ,  $\Theta$  compact; (ii)  $E(\sup_{\theta \in \Theta} |\nabla_{\theta} F(y_t|Z^t, \theta)_i|^{5+\psi}) \leq C < \infty$ ,  $i = 1, \dots, p$ , where  $\psi$  is the same positive constant defined in A1, and  $\nabla_{\theta} F(y_t|Z^{t-1}, \theta)_i$  is the  $i - th$  element of  $\nabla_{\theta} F(y_t|Z^{t-1}, \theta)$ ; (iii)  $F(u|Z^{t-1}, \theta)$  is twice differentiable on the interior of  $U \times \Theta$ , where  $U$  and  $\Theta$  are compact subsets of  $\mathfrak{R}$  and  $\mathfrak{R}^p$  respectively; and (iv)  $\nabla_{\theta} F(u|Z^{t-1}, \theta)$  and  $\nabla_{u,\theta} F(u|Z^{t-1}, \theta)$  are jointly continuous on  $U \times \Theta$  and  $4s$ -dominated on  $U \times \Theta$  for  $s > 3/2$ .

**CS3:** (i)  $\theta^{\dagger} = \arg \max_{\theta \in \Theta} E(\ln f(y_1|Z^0, \theta))$  is uniquely identified, (ii)  $f(y_t|Z^{t-1}, \theta)$  is twice continuously differentiable in  $\theta$  in the interior of  $\Theta$ , (ii) the elements of  $\nabla_{\theta} \ln f(y_t|Z^{t-1}, \theta)$  and of  $\nabla_{\theta}^2 \ln f(y_t|Z^{t-1}, \theta)$  are  $4s$ -dominated on  $\Theta$ , with  $s > 3/2$ ,  $E(-\nabla_{\theta}^2 \ln f(y_t|Z^{t-1}, \theta))$  is positive definite uniformly in  $\Theta$ .<sup>3</sup>

Of note is that **CS2** imposes mild smoothness and moment restrictions on the cumulative distribution function under the null, and is thus easily verifiable. Also, **CS2(i)-(ii)** in the study of the limiting behavior of  $V_{1T}$  and **CS2(iii)-(iv)** in the study of  $V_{2T}$ .

**Theorem 2.3 (from Theorem 1 in Corradi and Swanson (2003a)):** Let **CS1**, **CS2(i)-(ii)** and **CS3** hold. Then: (i) Under  $H_0$ ,  $V_{1T} \Rightarrow \sup_{r \in [0,1]} |V_1(r)|$ , where  $V$  is a zero mean Gaussian process with covariance

---

<sup>2</sup>For example, if  $f(Y|X_t, \theta_0) \sim N(\alpha X_t, \sigma^2)$ , then  $c_f^{0.95}(X_t) = 1.645 + \sigma \alpha X_t$ .

<sup>3</sup>Let  $\nabla_{\theta} \ln f(y_t|X_t, \theta)_i$  be the  $i - th$  element of  $\nabla_{\theta} \ln f(y_t|X_t, \theta)$ . For  $4s$ -domination on  $\Theta$ , we require  $|\nabla_{\theta} \ln f(y_t|X_t, \theta)_i| \leq m(X_t)$ , for all  $i$ , with  $E((m(X_t))^{4s}) < \infty$ , for some function  $m$ .

kernel  $K_1(r, r')$  given by:

$$\begin{aligned} E(V_1(r)V_1(r')) &= K_1(r, r') = E\left(\sum_{s=-\infty}^{\infty} (1\{F(y_1|Z^0, \theta_0) \leq r\} - r)(1\{F(y_s|Z^{s-1}, \theta_0) \leq r'\} - r')\right) \\ &\quad + E(\nabla_{\theta}F(x(r)|Z^{t-1}, \theta_0))' A(\theta_0) \sum_{s=-\infty}^{\infty} E(q_1(\theta_0)q_s(\theta_0)' A(\theta_0) E(\nabla_{\theta}F(x(r')|Z^{t-1}, \theta_0))) \\ &\quad - 2E(\nabla_{\theta}F(x(r)|Z^{t-1}, \theta_0))' A(\theta_0) \sum_{s=-\infty}^{\infty} E((1\{F(y_1|Z^0, \theta_0) \leq r\} - r) q_s(\theta_0)'), \end{aligned}$$

with  $q_s(\theta_0) = \nabla_{\theta} \ln f_s(y_s|Z^{s-1}, \theta_0)$ ,  $x(r) = F^{-1}(r|Z^{t-1}, \theta_0)$ , and  $A(\theta_0) = (E(\nabla_{\theta}q_s(\theta_0)\nabla_{\theta}q_s(\theta_0)'))^{-1}$ .

(ii) Under  $H_A$ , there exists an  $\varepsilon > 0$  such that  $\lim_{T \rightarrow \infty} \Pr\left(\frac{1}{T^{1/2}} V_{1T} > \varepsilon\right) = 1$ .

Notice that the limiting distribution is a zero mean Gaussian process, with a covariance kernel that reflects both dynamic misspecification as well as the contribution of parameter estimation error. Thus, the limiting distribution is not nuisance parameter free and so critical values cannot be tabulated.

Corradi and Swanson (2003a) also suggest another Kolmogorov test, which is no longer based on the probability integral transformation, but can be seen as an extension of the conditional Kolmogorov (CK) test of Andrews (1997) to the case of time series data and possible dynamic misspecification.

In a related important paper, Li and Tkacz (2004) discuss an interesting approach to testing for correct specification of the conditional density which involves comparing a nonparametric kernel estimate of the conditional density with the density implied under the null hypothesis. As in Hong and Li (2003) and Hong (2001), the Tkacz and Li test is characterized by a nonparametric rate. Of further note is that Whang (2000,2001) also proposes a version of Andrews' CK test for the correct specification, although his focus is on conditional mean, and not conditional distribution.

This test is constructed by comparing the empirical joint distribution of  $y_t$  and  $Z^{t-1}$  with the product of the distribution of  $y_t|Z^t$  and the empirical CDF of  $Z^{t-1}$ . In practice, the empirical joint distribution, say  $\widehat{H}_T(u, v) = \frac{1}{T} \sum_{t=1}^T 1\{y_t \leq u\} 1\{Z^{t-1} < v\}$ , and the semi-empirical/semi-parametric analog of  $F(u, v, \theta_0)$ , say  $\widehat{F}_T(u, v, \widehat{\theta}_T) = \frac{1}{T} \sum_{t=1}^T F(u|Z^{t-1}, \widehat{\theta}_T) 1\{Z^{t-1} < v\}$  are used, and the test statistic is:

$$V_{2T} = \sup_{u \times v \in U \times V} |V_{2T}(u, v)|, \tag{15}$$

where  $U$  and  $V$  are compact subsets of  $\Re$  and  $\Re^d$ , respectively, and

$$V_{2T}(u, v) = \frac{1}{\sqrt{T}} \sum_{t=1}^T \left( (1\{y_t \leq u\} - F(u|Z^{t-1}, \widehat{\theta}_T)) 1\{Z^{t-1} \leq v\} \right).$$

Note that  $V_{2T}$  is given in equation (3.9) of Andrews (1997).<sup>4</sup> Note also that when computing this statistic, a grid search over  $U \times V$  may be computationally demanding when  $V$  is high-dimensional. To avoid this problem, Andrews shows that when all  $(u, v)$  combinations are replaced with  $(y_t, X_t)$  combinations, the resulting test is asymptotically equivalent to  $V_{2T}(u, v)$ .

**Theorem 2.4 (from Theorem 2 in Corradi and Swanson (2003a)):**

Let **CS1**, **CS2**(iii)–(iv) and **CS3** hold. Then: (i) Under  $H_0$ ,  $V_{2T} \Rightarrow \sup_{u \times v \in U \times V} |Z(u, v)|$ , where  $V_{2T}$  is defined in (15) and  $Z$  is a zero mean Gaussian process with covariance kernel  $K_2(u, v, u', v')$  given by:

$$\begin{aligned} E\left(\sum_{s=-\infty}^{\infty} ((1\{y_1 \leq u\} - F(u|Z^0, \theta_0))1\{X_0 \leq v\})((1\{y_s \leq u'\} - F(u|Z^{s-1}, \theta_0))1\{X_s \leq v'\})\right) \\ + E(\nabla_{\theta}F(u|Z^0, \theta_0)'1\{Z^0 \leq v\})A(\theta_0)\sum_{s=-\infty}^{\infty} q_0(\theta_0)q_s(\theta_0)'A(\theta_0)E(\nabla_{\theta}F(u'|Z^0, \theta_0)1\{Z^0 \leq v'\}) \\ - 2\sum_{s=-\infty}^{\infty} ((1\{y_0 \leq u\} - F(u|Z^0, \theta_0))1\{Z^0 \leq v\})E(\nabla_{\theta}F(u'|Z^0, \theta_0)'1\{Z^0 \leq v'\})A(\theta_0)q_s(\theta_0)). \end{aligned}$$

(ii) Under  $H_A$ , there exists an  $\varepsilon > 0$  such that  $\lim_{T \rightarrow \infty} \Pr(\frac{1}{T^{1/2}}V_{2T} > \varepsilon) = 1$ .

As in Theorem 1.3, the limiting distribution is a zero mean Gaussian process with a covariance kernel that reflects both dynamic misspecification as well as the contribution of parameter estimation error. Thus, the limiting distribution is not nuisance parameter free and so critical values cannot be tabulated. Below, we outline a bootstrap procedure that takes into account the joint presence of parameter estimation error and possible dynamic misspecification.

## 2.5 Bootstrap Critical Values for the $V_{1T}$ and $V_{2T}$ Tests

Given that the limiting distributions of  $V_{1T}$  and  $V_{2T}$  are not nuisance parameter free, one approach is to construct bootstrap critical values for the tests. In order to show the first order validity of the bootstrap, it thus remains to obtain the limiting distribution of the bootstrapped statistic and show that it coincides with the limiting distribution of the actual statistic under  $H_0$ . Then, a test with correct asymptotic size and unit asymptotic power can be obtained by comparing the value of the original statistic with bootstrapped critical values.

If the data consists of *iid* observations, we should consider proceeding along the lines of Andrews (1997), by drawing  $B$  samples of  $T$  *iid* observations from the distribution under  $H_0$ , conditional on the observed

---

<sup>4</sup>Andrews (1997), for the case of *iid* observations, actually addresses the more complex situation where  $U$  and  $V$  are unbounded sets in  $R$  and  $R^d$ , respectively. We believe that an analogous result for the case of dependent observations holds, but showing this involves proofs for stochastic equicontinuity which are quite demanding.

values for the covariates,  $Z^{t-1}$ . The same approach could also be used in the case of dependence, if  $H_0$  were correct dynamic specification, (i.e. if  $Z^{t-1} = \mathfrak{S}_{t-1}$ ); in fact, in that case we could use a parametric bootstrap and draw observations from  $F(y_t|Z^t, \hat{\theta}_T)$ . However, if instead  $Z^{t-1} \subset \mathfrak{S}_{t-1}$ , using the parametric bootstrap procedure based on drawing observations from  $F(y_t|Z^{t-1}, \hat{\theta}_T)$  does not ensure that the long run variance of the resampled statistic properly mimics the long run variance of the original statistic; thus leading in general to the construction of invalid asymptotic critical values.

The approach used by Corradi and Swanson (2003a) involves comparing the empirical CDF of the resampled series, evaluated at the bootstrap estimator, with the empirical CDF of the actual series, evaluated at the estimator based on the actual data. For this, they use the overlapping block resampling scheme of Künsch (1989), as follows:<sup>5</sup> At each replication, draw  $b$  blocks (with replacement) of length  $l$  from the sample  $W_t = (y_t, X_t)$ , where  $T = lb$ . Thus, the first block is equal to  $W_{i+1}, \dots, W_{i+l}$ , for some  $i$ , with probability  $1/(T - l + 1)$ , the second block is equal to  $W_{i+1}, \dots, W_{i+l}$ , for some  $i$ , with probability  $1/(T - l + 1)$ , and so on for all blocks. More formally, let  $I_k$ ,  $k = 1, \dots, b$  be *iid* discrete uniform random variables on  $[0, 1, \dots, T - l]$ , and let  $T = bl$ . Then, the resampled series,  $W_t^* = (y_t^*, X_t^*)$ , is such that  $W_1^*, W_2^*, \dots, W_l^*, W_{l+1}^*, \dots, W_T^* = W_{I_1+1}, W_{I_1+2}, \dots, W_{I_1+l}, W_{I_2}, \dots, W_{I_b+l}$ , and so a resampled series consists of  $b$  blocks that are discrete *iid* uniform random variables, conditional on the sample. Also, let  $\hat{\theta}_T^*$  be the estimator constructed using the resampled series. For  $V_{1T}$ , the bootstrap statistic is:

$$V_{1T}^* = \sup_{r \in [0, 1]} |V_{1T}^*(r)|,$$

where

$$V_{1T}^*(r) = \frac{1}{\sqrt{T}} \sum_{t=1}^T \left( 1\{F(y_t^*|Z^{*,t-1}, \hat{\theta}_T^*) \leq r\} - 1\{F(y_t|Z^{t-1}, \hat{\theta}_T) \leq r\} \right), \quad (16)$$

and

$$\hat{\theta}_T^* = \arg \max_{\theta \in \Theta} \frac{1}{T} \sum_{t=1}^T \ln f(y_t^*|Z^{*,t-1}, \theta).$$

---

<sup>5</sup> Alternatively, one could use the stationary bootstrap of Politis and Romano (1994(a)(b)). The main difference between the block bootstrap and the stationary bootstrap of Politis and Romano (PR: 1994a) is that the former uses a deterministic block length, which may be either overlapping as in Künsch (1989) or non-overlapping as in Carlstein (1986), while the latter resamples using blocks of random length. One important feature of the PR bootstrap is that the resampled series, conditional on the sample, is stationary, while a series resampled from the (overlapping or non overlapping) block bootstrap is nonstationary, even if the original sample is strictly stationary. However, Lahiri (1999) shows that all block bootstrap methods, regardless of whether the block length is deterministic or random, have a first order bias of the same magnitude, but the bootstrap with deterministic block length has a smaller first order variance. In addition, the overlapping block bootstrap is more efficient than the non overlapping block bootstrap.

The rationale behind the choice of (16) is the following. By a mean value expansion it can be shown that,

$$\begin{aligned} V_{1T}^*(r) &= \frac{1}{\sqrt{T}} \sum_{t=1}^T (1\{F(y_t^*|Z^{*,t-1}, \theta^\dagger) \leq r\} - 1\{F(y_t|Z^{t-1}, \theta^\dagger) \leq r\}) \\ &\quad - \frac{1}{T} \sum_{t=1}^T \nabla_\theta F(y_t|Z^{t-1}, \theta^\dagger) \sqrt{T}(\hat{\theta}_T^* - \hat{\theta}_T) + o_{P^*}(1), \quad \text{Pr } P - P, \end{aligned} \quad (17)$$

where  $P^*$  denotes the probability law of the resampled series, conditional on the sample;  $P$  denotes the probability law of the sample; and where “ $o_{P^*}(1)$ ,  $\text{Pr } P - P$ ”, means a term approaching zero according to  $P^*$ , conditional on the sample and for all samples except a set of measure approaching zero. Now, the first term on the RHS of (17) can be treated via the empirical process version of the block bootstrap, suggesting that the term has the same limiting distribution as  $\frac{1}{\sqrt{T}} \sum_{t=1}^T (1\{F(y_t|Z^{t-1}, \theta^\dagger) \leq r\} - E(1\{F(y_t|Z^{t-1}, \theta^\dagger) \leq r\}))$ , where  $E(1\{F(y_t|X_t, \theta^\dagger) \leq r\}) = r$  under  $H_0$ , and is different from  $r$  under  $H_A$ , conditional of the sample. If  $\sqrt{T}(\hat{\theta}_T^* - \hat{\theta}_T)$  has the same limiting distribution as  $\sqrt{T}(\hat{\theta}_T - \theta^\dagger)$ , conditionally on the sample and for all samples except a set of measure approaching zero, then the second term on the RHS of (17) will properly capture the contribution of parameter estimation error to the covariance kernel. For the case of dependent observations, the limiting distribution of  $\sqrt{T}(\hat{\theta}_T^* - \hat{\theta}_T)$  for a variety of quasi maximum likelihood (QMLE) and GMM estimators has been examined in numerous papers in recent years.

For example, Hall and Horowitz (1996) and Andrews (2002) show that the block bootstrap provides improved critical values, in the sense of asymptotic refinement, for “studentized” GMM estimators and for tests of overidentifying restrictions, in the case where the covariance across moment conditions is zero after a given number of lags.<sup>6</sup> In addition, Inoue and Shintani (2004) show that the block bootstrap provides asymptotic refinements for linear overidentified GMM estimators for general mixing processes. In the present context, however, one cannot “studentize” the statistic, and we are thus unable to show second order refinement, as mentioned above. Instead, and again as mentioned above, the approach of Corradi and Swanson (2003a) is to show first order validity of  $\sqrt{T}(\hat{\theta}_T^* - \hat{\theta}_T)$ . An important recent contribution which is useful in the current context is that of Goncalves and White (2002,2004) who show that for QMLE estimators, the limiting distribution of  $\sqrt{T}(\hat{\theta}_T^* - \hat{\theta}_T)$  provides a valid first order approximation to that of  $\sqrt{T}(\hat{\theta}_T - \theta^\dagger)$  for heterogeneous and near epoch dependent series.

**Theorem 2.5 (from Theorem 3 of Corradi and Swanson (2003a):** Let **CS1**, **CS2(i)–(ii)** and **CS3**

---

<sup>6</sup>Andrews (2002) shows first order validity and asymptotic refinements of the equivalent  $k$ -step estimator of Davidson and MacKinnon (1999), which only requires the construction of a closed form expression at each bootstrap replication, thus avoiding nonlinear optimization at each replication.

hold, and let  $T = bl$ , with  $l = l_T$ , such that as  $T \rightarrow \infty$ ,  $l_T^2/T \rightarrow 0$ . Then,

$$P\left(\omega : \sup_{x \in \Re} \left| P^*[V_{1T}^*(\omega) \leq u] - P\left[\sup_{r \in [0,1]} \frac{1}{\sqrt{T}} \sum_{t=1}^T \left(1\{F(y_t | Z^{t-1}, \hat{\theta}_T) \leq r\} - E(1\{F(y_t | Z^{t-1}, \theta^\dagger) \leq r\})\right) \leq x\right]\right| > \varepsilon\right) \rightarrow 0.$$

Thus,  $V_{1T}^*$  has a well defined limiting distribution under both hypotheses, which under the null coincides with the same limiting distribution of  $V_{1T}$ ,  $\Pr - P$ , as  $E(1\{F(y_t | Z^{t-1}, \theta^\dagger) \leq r\}) = r$ . Now, define  $V_{2T}^* = \sup_{u \times v \in U \times V} |V_{2T}^*(u, v)|$ , where

$$V_{2T}^*(u, v) = \frac{1}{\sqrt{T}} \sum_{t=1}^T \left( (1\{y_t^* \leq u\} - F(u | Z^{*,t-1}, \hat{\theta}_T^*)) 1\{Z^{*,t-1} \leq v\} - (1\{y_t \leq u\} - F(u | Z^{t-1}, \hat{\theta}_T)) 1\{Z^{t-1} \leq v\} \right).$$

**Theorem 2.6 (from Theorem 4 of Corradi and Swanson (2003a):** Let **CS1**, **CS2**(iii)–(iv) and **CS3** hold, and let  $T = bl$ , with  $l = l_T$ , such that as  $T \rightarrow \infty$ ,  $l_T^2/T \rightarrow 0$ . Then,

$$\begin{aligned} & P\left(\omega : \sup_{x \in \Re} |P^*[V_{2T}^*(\omega) \leq x] \right. \\ & \quad \left. - P\left[\sup_{u \times v \in U \times V} \frac{1}{\sqrt{T}} \sum_{t=1}^T ((1\{y_t \leq u\} - F(u | Z^{t-1}, \hat{\theta}_T)) 1\{Z^{t-1} \leq v\} \right. \right. \\ & \quad \left. \left. - E((1\{y_t \leq u\} - F(u | Z^{t-1}, \theta^\dagger)) 1\{Z^{t-1} \leq v\})) \leq x\right] > \varepsilon\right) \\ & \rightarrow 0 \end{aligned}$$

In summary, from Theorems 2.5 and 2.6, we know that  $V_{1T}^*(\omega)$  (resp.  $V_{2T}^*(\omega)$ ) has a well defined limiting distribution, conditional on the sample and for all samples except a set of probability measure approaching zero. Furthermore, the limiting distribution coincides with that of  $V_{1T}$  (resp.  $V_{2T}$ ), under  $H_0$ . The above results suggest proceeding in the following manner. For any bootstrap replication, compute the bootstrapped statistic,  $V_{1T}^*$  (resp.  $V_{2T}^*$ ). Perform  $B$  bootstrap replications ( $B$  large) and compute the percentiles of the empirical distribution of the  $B$  bootstrapped statistics. Reject  $H_0$  if  $V_{1T}$  ( $V_{2T}$ ) is greater than the  $(1-\alpha)th$ -percentile. Otherwise, do not reject  $H_0$ . Now, for all samples except a set with probability measure approaching zero,  $V_{1T}$  ( $V_{2T}$ ) has the same limiting distribution as the corresponding bootstrapped statistic, under  $H_0$ . Thus, the above approach ensures that the test has asymptotic size equal to  $\alpha$ . Under the alternative,  $V_{1T}$  ( $V_{2T}$ ) diverges to infinity, while the corresponding bootstrap statistic has a well defined limiting distribution. This ensures unit asymptotic power. Note that the validity of the bootstrap critical values is based on an infinite number of bootstrap replications, although in practice we need to choose  $B$ . Andrews and Buchinsky (2000) suggest an adaptive rule for choosing  $B$ , Davidson and McKinnon (2000) suggest a pretesting procedure ensuring that there is a “small probability” of drawing different conclusions from the ideal bootstrap and from the bootstrap with  $B$  replications, for a test with a given level. However,

in the current context, the limiting distribution is a functional of a Gaussian process, so that the explicit density function is not known; and thus one cannot directly apply the approaches suggested in the papers above. In Monte Carlo experiments, Corradi and Swanson (2003a) show that finite sample results are quite robust to the choice of  $B$ . For example, they find that even for values of  $B$  as small as 100, the bootstrap has good finite sample properties.

Needless to say, if the parameters are estimated using  $T$  observations, and the statistic is constructed using only  $R$  observations, with  $R = o(T)$ , then the contribution of parameter estimation error to the covariance kernel is asymptotically negligible. In this case, it is not necessary to compute  $\hat{\theta}_T^*$ . For example, when bootstrapping critical values for a statistic analogous to  $V_{1T}$ , but constructed using  $R$  observations, say  $V_{1R}$ , one can instead construct  $V_{1R}^*$  as follows:

$$V_{1R}^* = \sup_{r \in [0,1]} \frac{1}{\sqrt{R}} \sum_{t=1}^R \left( 1\{F(y_t^* | Z^{*,t-1}, \hat{\theta}_T) \leq r\} - 1\{F(y_t | Z^{t-1}, \hat{\theta}_T) \leq r\} \right). \quad (18)$$

The intuition for this statistic is that  $\sqrt{R}(\hat{\theta}_T - \theta^\dagger) = o_p(1)$ , and so the bootstrap estimator of  $\theta$  is not needed in order to mimic the distribution of  $\sqrt{T}(\hat{\theta}_T - \theta^\dagger)$ . Analogs of  $V_{1R}$  and  $V_{1R}^*$  can similarly be constructed for  $V_{2T}$ . However, Corradi and Swanson (2003a) do not suggest using this approach because of the cost to finite sample power, and also because of the lack of an adaptive, data-driven rule for choosing  $R$ .

## 2.6 Tests Based on Normality Transformations

Most of the test statistics described above are based on testing for the uniformity on  $[0, 1]$  and/or independence of  $F_t(y_t | Z^{t-1}, \theta_0) = \int_{-\infty}^{y_t} f_t(y | Z^{t-1}, \theta_0)$ . Needless to say, if  $F_t(y_t | Z^{t-1}, \theta_0)$  is *iid UN* $[0, 1]$ , then  $\Phi^{-1}(F_t(y_t | Z^{t-1}, \theta_0))$ , where  $\Phi$  denotes the CDF of a standard normal, is *iidN*(0, 1).

Berkowitz (2001) has proposed a likelihood ratio test for the null of (standard) normal against autoregressive alternatives. The advantage of his test is that is really easy to implement and has standard limiting distribution, the disadvantage is that it has power only against specific alternatives.

Recently, Bontemps and Meddahi (BM: 2003a,b) introduce a novel approach to testing distributional assumptions. More precisely, they derive set of moment conditions which are satisfied under the null of a particular distribution. This leads to a GMM type test. Of interest is the fact that, BM (2003a) suggest a test for normality, based on regression residuals, which does not suffer of the parameter estimation error issue, as the contribution of estimation uncertainty vanishes asymptotically. However, BM (2003b) point out that, a test for the normality of  $\Phi^{-1}(F_t(y_t | Z^{t-1}, \theta_0))$  is instead affected by the contribution of estimation

uncertainty, because of the double transformation. Finally, other tests for normality have been recently suggested by Bai and Ng (2004) and by Duan (2003).

# 3 Specification Testing and Model Selection Out-of-Sample

In this section we revisit the tests of the previous section, except within the context of out-of-sample prediction, model selection, and evaluation. In addition, we discuss an alternative test based on a distributional mean square error analog. Before turning to our discussion of the tests, however, we first discuss estimation and parameter estimation error, two critical components of model selection and density accuracy testing.

EXTEND .....

## 3.1 Estimation and Parameter Estimation Error in Recursive and Rolling Estimation Schemes - West as well as West and McCracken Results

Tracing back to Granger (1980) Ashley, Granger and Schmalensee (1980), it has been noted that if we are interested in the predictive ability of different models, it should be of interest to evaluate them in an out of sample manner, namely by looking at predictions and associated prediction errors. This is particularly true if all models are assumed to be approximations of some “true” underlying unknown model (i.e. all models may be misspecified). In addition, it is noteworthy that sample evaluation may lead to model overfitting, a problem that can easily be avoided if out of sample evaluation is used. For an alternative view which is favorable to in sample evaluation, and which is sensible in a number of contexts, such as when the null model is assumed to be correctly specified, see the recent contribution of Inoue and Kilian (2004).

In out of sample model evaluation, the sample of  $T$  observation is split into  $R$  observations to be used for estimation, and  $P$  observations to be used for forecast construction, predictive density evaluation, and generally for model validation and selection. In this context, it is assumed that  $T = R + P$ . In out of sample contexts, parameters are usually estimated using either recursive or rolling estimation schemes. In both cases, one constructs a sequence of  $P$  estimators, which are in turn used in the construction of  $P$   $h$ -step ahead predictions and prediction errors, where  $h$  is the forecast horizon.

In the recursive estimation scheme, one constructs the first estimator using the first  $R$  observations, say  $\hat{\theta}_R$ , the second using observations up to  $R + 1$ , say  $\hat{\theta}_{R+1}$ , and so on until one has a sequence of  $P$  estimators,  $(\hat{\theta}_R, \hat{\theta}_{R+1}, \dots, \hat{\theta}_{R+P-1})$ . In the sequel, we consider the generic case of extremum estimators, or  $m$ -estimators, which include ordinary least squares, nonlinear least squares, and (quasi) maximum-likelihood estimators. Define the recursive estimator as:<sup>7</sup>

$$\hat{\theta}_t = \arg \min_{\theta \in \Theta} \frac{1}{t} \sum_{j=1}^t q(y_j, Z^{j-1}, \theta), \quad t = R, R + 1, \dots, R + P - 1, \quad (19)$$

where  $q(y_j, Z^{j-1}, \theta_i)$  denotes the objective function (i.e. in (quasi) MLE,  $q(y_j, Z^{j-1}, \theta_i) = -\ln f(y_j, Z^{j-1}, \theta_i)$ , with  $f$  denoting the (pseudo) density of  $y^t$  given  $Z^{t-1}$ ).<sup>8</sup>

In the rolling estimation scheme, one constructs a sequence of  $P$  estimators using a rolling window of  $R$  observations. That is, the first estimator is constructed using the first  $R$  observations, the second using observations from 2 to  $R + 1$ , and so on, with the last estimator being constructed using observations from  $T - R$  to  $T - 1$ , so that we have a sequence of  $P$  estimators,  $(\hat{\theta}_{R,R}, \hat{\theta}_{R+1,R}, \dots, \hat{\theta}_{R+P-1,R})$ .<sup>9</sup>

In general, it is common to assume that  $P$  and  $R$  grow as  $T$  grows. This assumption is maintained in the sequel. Notable exceptions to this approach are Giacomini and White (2003)<sup>10</sup>, who propose using a rolling scheme with a fixed window that does not increase with the sample size, so that estimated parameters are treated as mixing variables, and suggest an adaptive manner for choosing the window of observations, in order to take into account possible structure breaks.

Turning now to the rolling estimation scheme, define the relevant estimator as:

$$\hat{\theta}_{t,R} = \arg \min_{\theta \in \Theta} \frac{1}{R} \sum_{j=t-R+1}^t q(y_j, Z^{j-1}, \theta), \quad R \leq t \leq T - 1. \quad (20)$$

In the case of in sample model evaluation, the contribution of parameter estimation error is summarized by the limiting distribution of  $\sqrt{T}(\hat{\theta}_T - \theta^\dagger)$ , where  $\theta^\dagger$  is the probability limit of  $\hat{\theta}_T$ . This is clear, for example, from the proofs of Theorems 2.3 and 2.4 above, which are given in Corradi and Swanson (2003a). On the other

<sup>7</sup>For notational simplicity, we begin all summations at  $t = 1$ . Note, however, that in general if  $Z^{t-1}$  contains information up to the  $s^{th}$  lag, say, then summation should be initiated at  $t = s + 1$ .

<sup>8</sup>Generalized method of moments (GMM) estimators can be treated in an analogous manner. As one is often interested in comparing misspecified models, we avoid using overidentified GMM estimators in our discussion. This is because, as pointed out by Hall and Inoue (2003), one cannot obtain asymptotic normality for overidentified GMM in the misspecified case.

<sup>9</sup>Here, for simplicity, we have assumed that in sample estimation ends with period  $T - R$  to  $T - 1$ . Thus, we are implicitly assuming that  $h = 1$ , so that  $P$  out of sample predictions and prediction errors can be constructed.

<sup>10</sup>The Giacomini and White (2003) test is designed for conditional mean evaluation, although it can likely be easily extended to the case of conditional density evaluation. One important advantage of this test is that it is valid for both nested and nonnested models (see below for further discussion).

hand, in the case of recursive and rolling estimation schemes, the contribution of parameter estimation error is summarized by the limiting distribution of  $\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_t - \theta^\dagger)$  and  $\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_{t,R} - \theta^\dagger)$ . Under mild conditions, because of the central limit theorem,  $(\hat{\theta}_t - \theta^\dagger)$  and  $(\hat{\theta}_{t,R} - \theta^\dagger)$  are  $O_P(R^{-1/2})$ . Thus, if  $P$  grows at a slower rate than  $R$  (i.e. if  $P/R \rightarrow 0$ , as  $T \rightarrow \infty$ ), then  $\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_t - \theta^\dagger)$  and  $\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_{t,R} - \theta^\dagger)$  are asymptotically negligible. In other words, if the in sample portion of the data used for estimation is “much larger” than the out of sample portion of the data to be used for predictive accuracy testing and generally for model evaluation, then the contribution of parameter estimation error is asymptotically negligible.

A key result which is used in all of the subsequent limiting distribution results discussed in this chapter is the derivation of the limiting distribution of  $\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_t - \theta^\dagger)$  (see West (1996)) and of  $\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_{t,R} - \theta^\dagger)$  (see West and McCracken (1998)). Their results follow, given the following assumptions.

**W1:**  $(y_t, Z^{t-1})$ , with  $y_t$  scalar and  $Z^{t-1}$  an  $R^\zeta$ -valued ( $0 < \zeta < \infty$ ) vector, is a strictly stationary and absolutely regular  $\beta$ -mixing process with size  $-4(4 + \psi)/\psi$ ,  $\psi > 0$ .

**W2:** (i)  $\theta_i^\dagger$  is uniquely identified (i.e.  $E(q(y_t, Z^{t-1}, \theta)) > E(q(y_t, Z^{t-1}, \theta_i^\dagger))$  for any  $\theta_i \neq \theta_i^\dagger$ ); (ii)  $q$  is twice continuously differentiable on the interior of  $\Theta$ , and for  $\Theta_i$  a compact subset of  $R^\varrho$ ; (iii) the elements of  $\nabla_\theta q$  and  $\nabla_{\theta_i}^2 q$  are  $p$ -dominated on  $\Theta$ , with  $p > 2(2 + \psi)$ , where  $\psi$  is the same positive constant as defined in **W1**; and (iii)  $E(-\nabla_{\theta_i}^2 q(\theta))$  is negative definite uniformly on  $\Theta_i$ .

**Theorem 3.1 (from Lemma 4.1 and Theorem 4.1 in West (1996)):**

Let **W1** and **W2** hold. Also, as  $T \rightarrow \infty$ ,  $P/R \rightarrow \pi$ ,  $0 < \pi < \infty$ . Then,

$$\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_t - \theta^\dagger) \xrightarrow{d} N(0, 2\Pi A^\dagger C_{00} A^\dagger),$$

where  $\Pi = (1 - \pi^{-1} \ln(1 + \pi))$ ,  $C_{00} = \sum_{j=-\infty}^{\infty} E \left( (\nabla_\theta q(y_{1+s}, Z^s, \theta^\dagger)) (\nabla_\theta q(y_{1+s+j}, Z^{s+j}, \theta^\dagger))' \right)$ , and  $A^\dagger = E(-\nabla_{\theta_i}^2 q(y_t, Z^{t-1}, \theta^\dagger))$ .

**Theorem 3.2 (from Lemmas 4.1 and 4.2 in West (1996) and McCracken (1998)):**

Let **W1** and **W2** hold. Also, as  $T \rightarrow \infty$ ,  $P/R \rightarrow \pi$ ,  $0 < \pi < \infty$ . Then,

$$\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_{t,R} - \theta^\dagger) \xrightarrow{d} N(0, 2\Pi C_{00}),$$

where for  $\pi \leq 1$ ,  $\Pi = \pi - \frac{\pi^2}{3}$  and for  $\pi > 1$ ,  $\Pi = 1 - \frac{1}{3\pi}$ . Also,  $C_{00}$  and  $A^\dagger$  defined as in Theorem 3.1.

### 3.2 Out-of-Sample Implementation of Bai as well as Hong and Li Tests

We begin by analyzing the out of sample versions of Bai's (2003) test. Define the out of sample version of the statistic in (6) for the recursive case, as

$$\widehat{V}_{P,rec} = \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( 1\{F_{t+1}(y_{t+1}|Z^t, \widehat{\theta}_t) \leq r\} - r \right), \quad (21)$$

and for the rolling case as

$$\widehat{V}_{P,rol} = \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( 1\{F_{t+1}(y_{t+1}|Z^t, \widehat{\theta}_{t,R}) \leq r\} - r \right), \quad (22)$$

where  $\widehat{\theta}_t$  and  $\widehat{\theta}_{t,R}$  are defined as in (19) and (20), respectively. Also, define

$$\widehat{W}_{P,rec}(r) = \widehat{V}_{P,rec}(r) - \int_0^r \left( \dot{g}(s) C^{-1}(s) \dot{g}(s)' \int_s^1 \dot{g}(\tau) d\widehat{V}_{P,rec}(\tau) \right) ds$$

and

$$\widehat{W}_{P,rol}(r) = \widehat{V}_{P,rol}(r) - \int_0^r \left( \dot{g}(s) C^{-1}(s) \dot{g}(s)' \int_s^1 \dot{g}(\tau) d\widehat{V}_{P,rol}(\tau) \right) ds$$

Let **BAI1**, **BAI2** and **BAI4** be as given in Section 2.1, and modify **BAI3** as follows:

**BAI3'**:  $(\widehat{\theta}_t - \theta_0) = O_P(P^{-1/2})$ , uniformly in  $t$ .<sup>11</sup>

**BAI3''**:  $(\widehat{\theta}_{t,R} - \theta_0) = O_P(P^{-1/2})$ , uniformly in  $t$ .<sup>12</sup>

Given this setup, the following proposition holds.

**Proposition 3.2:** Let **BAI1**, **BAI2**, **BAI4** hold and assume that as  $T \rightarrow \infty$ ,  $P/R \rightarrow \pi$ , with  $\pi < \infty$ . Then,

(i) If **BAI3'** hold, under the null hypothesis in (1),  $\sup_{r \in [0,1]} \widehat{W}_{P,rec}(r) \xrightarrow{d} \sup_{r \in [0,1]} W(r)$ .

(ii) If **BAI3''** hold, under the null hypothesis in (1),  $\sup_{r \in [0,1]} \widehat{W}_{P,rol}(r) \xrightarrow{d} \sup_{r \in [0,1]} W(r)$ .

**Proof:** See Appendix.

---

<sup>11</sup>Note that BAI3' is satisfied under mild conditions, provided  $P/R \rightarrow \pi$  with  $\pi < \infty$ . In particular,

$$P^{1/2} (\widehat{\theta}_t - \theta_0) = \left( \frac{1}{t} \sum_{j=1}^t \nabla_\theta^2 q_j(\bar{\theta}_t) \right)^{-1} \left( \frac{P^{1/2}}{t} \sum_{j=1}^t \nabla_\theta q_j(\theta_0) \right)$$

Now, by uniform law of large numbers,  $\left( \frac{1}{t} \sum_{j=1}^t \nabla_\theta^2 q_j(\bar{\theta}_t) \right)^{-1} - \left( \frac{1}{t} \sum_{j=1}^t E(\nabla_\theta^2 q_j(\theta_0)) \right)^{-1} \xrightarrow{pr} 0$ . Let  $t = [Tr]$ , with  $(1 + \pi)^{-1} \leq r \leq 1$ . Then,

$$\frac{P^{1/2}}{[Tr]} \sum_{j=1}^{[Tr]} \nabla_\theta q_j(\theta_0) = \sqrt{\frac{P}{T}} \frac{1}{r} \frac{1}{\sqrt{T}} \sum_{j=1}^{[Tr]} \nabla_\theta q_j(\theta_0).$$

For any  $r$ ,  $\frac{1}{r} \frac{1}{\sqrt{T}} \sum_{j=1}^{[Tr]} \nabla_\theta q_j(\theta_0)$  satisfies a CLT and so is  $O_P(T^{-1/2})$  and so  $O(P^{-1/2})$ . As  $r$  is bounded away from zero, and because of stochastic equicontinuity in  $r$ ,  $\sup_{r \in [(1+\pi)^{-1}, 1]} \sqrt{\frac{P}{T}} \frac{1}{r} \frac{1}{\sqrt{T}} \sum_{j=1}^{[Tr]} \nabla_\theta q_j(\theta_0) = O_P(P^{-1/2})$ .

<sup>12</sup>BAI3'' is also satisfied under mild assumptions, by the same arguments used in the footnote above.

Turning now to an out of sample version of the Hong and Li test, note that these tests can be defined as in equations (8)-(11) above, by replacing  $\widehat{U}_t$  in (8) with  $\widehat{U}_{t,rec}$  and  $\widehat{U}_{t,rol}$ , respectively, where

$$\widehat{U}_{t+1,rec} = F_{t+1}(y_{t+1}|Z^t, \widehat{\theta}_t), \text{ and } \widehat{U}_{t+1,rol} = F_{t+1}(y_{t+1}|Z^t, \widehat{\theta}_{t,R}), \quad (23)$$

with  $\widehat{\theta}_t$  and  $\widehat{\theta}_{t,R}$  defined as in (19) and (20). Thus, for the recursive estimation case, it follows that

$$\widehat{\phi}_{rec}(u_1, u_2) = (P - j)^{-1} \sum_{\tau=R+j+1}^{T-1} K_h(u_1, \widehat{U}_{\tau,rec}) K_h(u_2, \widehat{U}_{\tau-j,rec}),$$

where  $n = T = R + P$ . For the rolling estimation case, it follows that

$$\widehat{\phi}_{rol}(u_1, u_2) = (P - j)^{-1} \sum_{\tau=R+j+1}^{T-1} K_h(u_1, \widehat{U}_{\tau,rol}) K_h(u_2, \widehat{U}_{\tau-j,rol}).$$

Also, define

$$\widehat{M}_{rec}(j) = \int_0^1 \int_0^1 (\widehat{\phi}_{rec}(u_1, u_2) - 1)^2 du_1 du_2, \quad \widehat{M}_{rol}(j) = \int_0^1 \int_0^1 (\widehat{\phi}_{rol}(u_1, u_2) - 1)^2 du_1 du_2$$

and

$$\widehat{Q}_{rec}(j) = ((n - j)\widehat{M}_{rec}(j) - A_h^0) / V_0^{1/2}, \quad \widehat{Q}_{rol}(j) = ((n - j)\widehat{M}_{rol}(j) - A_h^0) / V_0^{1/2}.$$

The following proposition then holds.

**Proposition 3.3:** Let **HL1-HL4** hold. If  $h = cP^{-\delta}$ ,  $\delta \in (0, 1/5)$ , then under the null in (1), and for any  $j > 0$ ,  $j = o(P^{1-\delta(5-2/v)})$ , if as  $P, R \rightarrow \infty$ ,  $P/R \rightarrow \pi$ ,  $\pi < \infty$ ,  $\widehat{Q}_{rec}(j) \xrightarrow{d} N(0, 1)$  and  $\widehat{Q}_{rol}(j) \xrightarrow{d} N(0, 1)$ .

The statement in the proposition above follows straightforwardly by the same arguments used in the proof of Theorem 1 in Hong and Li (2003). Additionally, and as noted above, the contribution of parameter estimation error is of order  $O_P(P^{1/2})$ , while the statistic converges at a nonparametric rate, depending on the bandwidth parameter. Therefore, regardless of the estimation scheme used, the contribution of parameter estimation error is asymptotically negligible.

### 3.3 Out-of-Sample Implementation of Corradi and Swanson Tests

We now outline out of sample versions of the Corradi and Swanson (2003a) tests. First, redefine the statistics using the above out of sample notation as

$$V_{1P,rec} = \sup_{r \in [0,1]} |V_{1P,rec}(r)|, \quad V_{1P,rol} = \sup_{r \in [0,1]} |V_{1P,rol}(r)|$$

where

$$V_{1P,rec}(r) = \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( \mathbb{1}\{\widehat{U}_{t+1,rec} \leq r\} - r \right)$$

and

$$V_{1P,rol}(r) = \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( 1\{\widehat{U}_{t+1,rol} \leq r\} - r \right),$$

with  $\widehat{U}_{t,rec}$  and  $\widehat{U}_{t,rol}$  defined as in (23). Further, define

$$V_{2P,rec} = \sup_{u \times v \in U \times V} |V_{2P,rec}(u, v)|, \quad V_{2P,rol} = \sup_{u \times v \in U \times V} |V_{2P,rol}(u, v)|,$$

where

$$V_{2P,rec}(u, v) = \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( (1\{y_{t+1} \leq u\} - F(u|Z^t, \widehat{\theta}_t)) 1\{Z^t \leq v\} \right)$$

and

$$V_{2P,rol}(u, v) = \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( (1\{y_{t+1} \leq u\} - F(u|Z^t, \widehat{\theta}_{t,R})) 1\{Z^t \leq v\} \right).$$

Hereafter, let  $V_{1P,J} = V_{1P,rec}$  when  $J = 1$  and  $V_{1P,J} = V_{1P,rol}$  when  $J = 2$  and similarly,  $V_{2P,J} = V_{2P,rec}$  when  $J = 1$  and  $V_{2P,J} = V_{2P,rol}$  when  $J = 2$ . The following propositions then hold.

**Proposition 3.4:** Let **CS1**, **CS2(i)–(ii)** and **CS3** hold. Also, as  $P, R \rightarrow \infty$ ,  $P/R \rightarrow \pi$ ,  $0 < \pi < \infty$ .<sup>13</sup> Then for  $J = 1, 2$ : (i) Under  $H_0$ ,  $V_{1P,J} \Rightarrow \sup_{r \in [0,1]} |V_{1,J}(r)|$ , where  $V_{1,J}$  is a zero mean Gaussian process with covariance kernel  $K_{1,J}(r, r')$  given by:

$$\begin{aligned} K_{1,J}(r, r') &= E \left( \sum_{s=-\infty}^{\infty} (1\{F(y_1|Z^0, \theta_0) \leq r\} - r) (1\{F(y_s|Z^{s-1}, \theta_0) \leq r'\} - r') \right) \\ &\quad + \Pi_J E(\nabla_{\theta} F(x(r)|Z^{t-1}, \theta_0))' A(\theta_0) \sum_{s=-\infty}^{\infty} E(q_1(\theta_0) q_s(\theta_0)' A(\theta_0) E(\nabla_{\theta} F(x(r')|Z^{t-1}, \theta_0))) \\ &\quad - 2C\Pi_J E(\nabla_{\theta} F(x(r)|Z^{t-1}, \theta_0))' A(\theta_0) \sum_{s=-\infty}^{\infty} E((1\{F(y_1|Z^0, \theta_0) \leq r\} - r) q_s(\theta_0)') \end{aligned}$$

with  $q_s(\theta_0) = \nabla_{\theta} \ln f_s(y_s|Z^{s-1}, \theta_0)$ ,  $x(r) = F^{-1}(r|Z^{t-1}, \theta_0)$ ,  $A(\theta_0) = (E(\nabla_{\theta} q_s(\theta_0) \nabla_{\theta} q_s(\theta_0)'))^{-1}$ ,  $\Pi_1 =$

$2(1 - \pi^{-1} \ln(1 + \pi))$ , and  $C\Pi_1 = (1 - \pi^{-1} \ln(1 + \pi))$ . For  $J = 2$ ,  $j = 1$  and  $P \leq R$ ,  $\Pi_2 = \left(\pi - \frac{\pi^2}{3}\right)$ ,  $C\Pi_2 = \frac{\pi}{2}$ , and for  $P > R$ ,  $\Pi_2 = \left(1 - \frac{1}{3\pi}\right)$  and  $C\Pi_2 = \left(1 - \frac{1}{2\pi}\right)$ .

(ii) Under  $H_A$ , there exists an  $\varepsilon > 0$  such that  $\lim_{T \rightarrow \infty} \Pr(\frac{1}{P^{1/2}} V_{1T,J} > \varepsilon) = 1$ ,  $J = 1, 2$ .

**Proof:** See Appendix.

**Proposition 3.5:** Let **CS1**, **CS2(iii)–(iv)** and **CS3** hold. Also, as  $P, R \rightarrow \infty$ ,  $P/R \rightarrow \pi$ ,  $0 < \pi < \infty$ . Then for  $J = 1, 2$ : (i) Under  $H_0$ ,  $V_{2P,J} \Rightarrow \sup_{u \times v \in U \times V} |Z_J(u, v)|$ , where  $V_{2P,J}$  is defined as in (15) and  $Z$  is a zero

---

<sup>13</sup>Note that for  $\pi = 0$ , the contribution of parameter estimation error is asymptotically negligible, and so the covariance kernel is the same as that given in Theorem 2.3.

mean Gaussian process with covariance kernel  $K_{2,J}(u, v, u', v')$  given by:

$$\begin{aligned} & E\left(\sum_{s=-\infty}^{\infty} ((1\{y_1 \leq u\} - F(u|Z^0, \theta_0))1\{X_0 \leq v\})((1\{y_s \leq u'\} - F(u|Z^{s-1}, \theta_0))1\{X_s \leq v'\})\right) \\ & + \Pi_J E(\nabla_{\theta} F(u|Z^0, \theta_0)' 1\{Z^0 \leq v\}) A(\theta_0) \sum_{s=-\infty}^{\infty} q_0(\theta_0) q_s(\theta_0)' A(\theta_0) E(\nabla_{\theta} F(u'|Z^0, \theta_0) 1\{Z^0 \leq v'\}) \\ & - 2C\Pi_J \sum_{s=-\infty}^{\infty} ((1\{y_0 \leq u\} - F(u|Z^0, \theta_0))1\{Z^0 \leq v\}) E(\nabla_{\theta} F(u'|Z^0, \theta_0)' 1\{Z^0 \leq v'\}) A(\theta_0) q_s(\theta_0). \end{aligned}$$

where  $\Pi_J$  and  $C\Pi_J$  are defined as in the statement of Proposition 3.4.

(ii) Under  $H_A$ , there exists an  $\varepsilon > 0$  such that  $\lim_{T \rightarrow \infty} \Pr(\frac{1}{T^{1/2}} V_{2T} > \varepsilon) = 1$ .

**Proof:** See Appendix.

It is immediate to see that the limiting distributions in Propositions 3.4 and 3.5 differ from the ones in Theorems 2.3 and 2.4 only up terms  $\Pi_j$  and  $C\Pi_j$ ,  $j = 1, 2$ . On the other hand, we shall see that valid asymptotic critical values cannot be obtained by directly following the bootstrap procedure described in Section 2.5. Below, we outline how to obtain valid bootstrap critical values in the recursive and in the rolling estimation cases, respectively.

### 3.4 Bootstrap Critical for the $V_{1P,J}$ and $V_{2P,J}$ Tests Under Recursive Estimation

In the recursive estimation case, earlier observations are used more frequently than temporally subsequent observations. In fact, the first  $R$  observations are used  $P$  times, whereas the last observation is used only once. This introduces a location bias to the usual block bootstrap, as under standard resampling with replacement schemes, any block from the original sample has the same probability of being selected. Such a location bias can be either positive or negative, depending on the sample that we observe. One way to circumvent this problem by first forming bootstrap samples as follows: Resample  $R$  observations from the initial  $R$  sample observations, and then concatenate onto this vector an additional  $P$  resampled observations from the remaining sample. Thereafter, construct  $\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_t^* - \hat{\theta}_t)$  and add an adjustment term in order to ensure that the distribution of the sum of both components is the same as the distribution of  $\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_t - \theta^\dagger)$ , conditional on the sample, and for all samples except a set of probability measure approaching zero. The adjustment term compensates for the fact that, when resampling from the last  $P$  observations, each block (of length  $l$ ) has the same chance of being drawn, while in the construction of the actual estimator, earlier observations are more heavily used. In addition to this split sample approach, we later discuss a “full sample” block bootstrap procedure that is appropriate for the predictive density and accuracy tests in this chapter,

and which is based on resampling from the whole sample. However, in the full sample case we need more “complicated” adjustment terms in order to offset the bias term.

### 3.4.1 Split Sample Recursive PEE Bootstrap

Begin by resampling  $R$  observations from the initial  $R$  sample observations, and then concatenating onto this an additional  $P$  observations resampled from the  $P$  remaining sample observations. More specifically, let  $b_1 l_1 + b_2 l_2 = T + 1$ , with  $b_1 l_1 = R + 1$  and  $b_2 l_2 = P$ . Also, let  $W_t = (y_t, Z^{t-1})$ . First, draw  $b_1$  overlapping blocks, of length  $l_1$ , from  $1, \dots, R$  and then draw  $b_2$  overlapping blocks, of length  $l_2$ , from data indexed by  $R+1, \dots, R+P$ , with replacement. The first  $R+1$  pseudo observations,  $W_1^*, W_{s+1}^*, \dots, W_{s+l-1}^*, \dots, W_R^*$ , are equal to  $W_{I_1^R}, W_{I_1^R+1}, \dots, W_{I_1^R+l_1-1}, \dots, W_{I_{b_1}^R+l_1-1}$ , where  $I_i^R, i = 1, \dots, b_1$  are independent uniform random draws on the interval  $1, \dots, R - l_1 + 1$ ; and the remaining  $P$  pseudo observations,  $W_{R+1}^*, W_{R+2}^*, \dots, W_{R+l}^*, \dots, W_{R+P}^*$ , are equal to  $W_{I_1^P}, W_{I_1^P+1}, \dots, W_{I_1^P+l_2-1}, \dots, W_{I_{b_2}^P+l_2-1}$ , where  $I_i^P, i = 1, \dots, b_2$  are independent uniform random draws from data indexed by  $R + 1, R + 2, \dots, R + P - l - 1$ . Thus, conditional on the (entire) sample, the pseudo time series  $W_t^*, t = 2, \dots, R, R + 1, \dots, R + P$ , consists of  $b = b_1 + b_2$  asymptotically independent, but non identically distributed blocks of length  $l_1$  and  $l_2$  respectively. Also, conditionally on the sample, all of the moments of each block are asymptotically homogeneous, under the assumption that the underlying sample is strictly stationary. Therefore, the rescaled (partial) sums of the blocks satisfy the law of large numbers and the central limit theorem for asymptotically independent and homogeneous random variables, conditional on the (entire) sample. Now, define the recursive PEE bootstrap  $m$ -estimator as,

$$\widehat{\theta}_t^* = \arg \min_{\theta_i \in \Theta_i} \frac{1}{t} \sum_{j=1}^t q(y_j^*, Z^{*,j-1}, \theta), \quad R \leq t \leq T - 1. \quad (24)$$

Further, define:

$$\begin{aligned} \Psi_{R,P}^* &= \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( \widehat{\theta}_t^* - \widehat{\theta}_t \right) + \left( -\frac{1}{T} \sum_{t=1}^T \nabla_{\theta_i}^2 q(y_t, Z^{t-1}, \widehat{\theta}_{T-1}) \right)^{-1} \\ &\quad \times \frac{1}{\sqrt{P}} \sum_{j=1}^{P-1} a_{R,j} \left( \nabla_{\theta} q(y_{R+j}, Z^{R+j-1}, \widehat{\theta}_{T-1}) - \frac{1}{P} \sum_{j=1}^P \nabla_{\theta} q(y_{R+j}, Z^{R+j-1}, \widehat{\theta}_{T-1}) \right), \end{aligned} \quad (25)$$

where  $a_{R,j} = \frac{1}{R+j} + \frac{1}{R+j+1} + \dots + \frac{1}{R+P-1}$ .

As can be seen from (25), if as  $P, R \rightarrow \infty$ ,  $P/R \rightarrow \pi = 0$ , then both terms on the RHS of (25) approach zero and so  $\Psi_{R,P}^* \xrightarrow{pr} 0$ . This is not surprising, as in this case parameter estimation error vanishes and so  $\Psi_{R,P}^*$  properly mimics something going to zero in probability. Therefore, if  $\pi = 0$ , there is no need at all

to use a correction term when constructing the bootstrap statistic. The following result pertains given the above setup.

**Theorem 3.6 (from Theorem 1 in Corradi and Swanson (2003b):** Let **CS1** and **CS3** hold. Also, assume that as  $P, R \rightarrow \infty$ ,  $P/R \rightarrow \pi$ ,  $0 < \pi < \infty$ , and that as  $l_1, l_2 \rightarrow \infty$ ,  $\frac{l_2}{P^{1/4}} \rightarrow 0$  and  $\frac{l_1}{R^{1/4}} \rightarrow 0$ . Then,

$$P\left(\omega : \sup_{v \in \mathbb{R}^{\varrho(i)}} \left| P_{R,P}^*(\Psi_{R,P}^* \leq v) - P\left(\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\widehat{\theta}_{i,t} - \theta_i^\dagger) \leq v\right)\right| > \varepsilon\right) \rightarrow 0,$$

where  $P_{R,P}^*$  denotes the probability law of the resampled series, conditional on the (entire) sample.

Broadly speaking, Theorem 3.6 states that  $\Psi_{R,P}^*$  has the same limiting distribution as  $\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\widehat{\theta}_{i,t} - \theta_i^\dagger)$ , conditional on sample, and for all samples except a set with probability measure approaching zero. Though a detailed proof of Theorem 3.6 is given in the Corradi and Swanson (2003b), it is worthwhile to give an intuitive explanation of why there is an adjustment term in  $\Psi_{R,P}^*$ . For notational simplicity, let  $h_{i,t} = \nabla_{\theta_i} q_i(y_t, Z^{t-1}, \theta_i^\dagger)$  and  $h_{i,t}^* = \nabla_{\theta_i} q_i(y_t^*, Z^{*,t-1}, \theta_i^\dagger)$ . Via a mean value expansion around  $\theta^\dagger$ , using a similar argument as in Lemma A5 in West (1996), it follows that

$$\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\widehat{\theta}_{i,t} - \theta_i^\dagger) = B_i^\dagger \frac{a_{R,0}}{\sqrt{P}} \sum_{t=s}^R h_{i,t} + B_i^\dagger \frac{1}{\sqrt{P}} \sum_{j=1}^{P-1} a_{R,j} h_{i,R+j} + o_P(1), \quad (26)$$

where  $B_i^\dagger = \left(E(-\nabla_{\theta_i}^2 q_i(y_t, Z^{t-1}, \theta_i^\dagger))\right)^{-1}$ . Also,

$$\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\widehat{\theta}_{i,t}^* - \widehat{\theta}_{i,t}) = B_i^\dagger \frac{a_{R,0}}{\sqrt{P}} \sum_{t=s}^R (h_{i,t}^* - h_{i,t}) + B_i^\dagger \frac{1}{\sqrt{P}} \sum_{j=1}^{P-1} a_{R,j} (h_{i,R+j}^* - h_{i,R+j}) + o_P^*(1), \quad \text{Pr } -P. \quad (27)$$

Now, the first term on the RHS of (27) has the same limiting distribution as the first term on the RHS of (26), conditional on sample. However, the second term on the RHS of (27) does not have the same limiting distribution as the second term on the RHS of (26), conditional on sample. The reason for this is that, up to a term of order  $O_P^*\left(l/\sqrt{P}\right)$ ,  $E^*\left(\frac{1}{\sqrt{P}} \sum_{j=1}^{P-1} a_{R,j} h_{i,R+j}^*\right) = \frac{1}{\sqrt{P}} \sum_{j=1}^{P-1} a_{R,j} \frac{1}{P} \sum_{j=1}^{P-1} h_{i,R+j} \neq \frac{1}{\sqrt{P}} \sum_{j=1}^{P-1} a_{R,j} h_{i,R+j}$ . Now, rewrite (27) as,

$$\begin{aligned} \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\widehat{\theta}_{i,t}^* - \widehat{\theta}_{i,t}) &= \left[ B_i^\dagger \frac{a_{R,0}}{\sqrt{P}} \sum_{t=s}^R (h_{i,t}^* - h_{i,t}) + B_i^\dagger \frac{1}{\sqrt{P}} \sum_{j=1}^{P-1} a_{R,j} \left(h_{i,R+j}^* - \frac{1}{P} \sum_{j=1}^{P-1} h_{i,j}\right) \right] \\ &\quad - B_i^\dagger \frac{1}{\sqrt{P}} \sum_{j=1}^{P-1} a_{R,j} \left(h_{i,R+j} - \frac{1}{P} \sum_{j=1}^{P-1} h_{i,j}\right) + o_P^*(1), \quad \text{Pr } -P. \end{aligned} \quad (28)$$

As proven in Corradi and Swanson (2003b), the term in square brackets in (28) mimics the limiting distribution of  $\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\widehat{\theta}_{i,t} - \theta_i^*)$ , conditional on sample. Also, the difference between the second term on the RHS of (25) and  $B_i^\dagger \frac{1}{\sqrt{P}} \sum_{j=1}^{P-1} a_{R,j} \left(h_{i,R+j} - \frac{1}{P} \sum_{j=1}^{P-1} h_{i,j}\right)$ , vanishes asymptotically. Therefore, the adjustment term completely offsets the second term on the RHS of (28), as  $R, P$  go to infinity.

### 3.4.2 Full Sample Recursive PEE Bootstrap

Suppose one instead resamples  $P+R$  observations from the entire sample. Let let  $W_t = (y_t, Z^{t-1})$ , and draw  $b$  overlapping blocks of length  $l$ , where  $bl = T - s$ . The resampled observations,  $W_1^{**}, W_2^{**}, \dots, W_l^{**}, \dots, W_T^{**}$ , are equal to  $W_{I_1}, W_{I_1+1}, \dots, W_{I_1+l-1}, \dots, W_{I_b+l-1}$ , where  $I_i, i = 1, \dots, b$  are independent uniform random draws on the interval  $1, \dots, T - l + 1$ . Let  $\hat{\theta}_t^{**}$  be defined as in (24), but using  $W_t^{**}$  instead of  $W_t^*$ . Also, let  $h_{i,t}^{**} = \nabla_{\theta_i} q_i(y_t^{**}, Z^{**}, t-1, \theta_i^\dagger)$ . Now,

$$\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_{i,t}^{**} - \hat{\theta}_{i,t}) = B_i^\dagger \frac{a_{R,0}}{\sqrt{P}} \sum_{t=s}^R (h_{i,t}^{**} - h_{i,t}) + B_i^\dagger \frac{1}{\sqrt{P}} \sum_{j=1}^{P-1} a_{R,j} (h_{i,R+j}^{**} - h_{i,R+j}) + o_P^*(1), \quad \text{Pr } -P. \quad (29)$$

Note that up to an error of order  $O\left(\frac{l}{\sqrt{T}}\right)$ ,  $\text{Pr } -P$ ,  $E^{**}\left(\frac{a_{R,0}}{\sqrt{P}} \sum_{t=s}^R h_{i,t}^{**}\right) = \frac{a_{R,0}(R-s)}{\sqrt{P}} \bar{h}_T$ , and  $E^{**}\left(\frac{1}{\sqrt{P}} \sum_{j=1}^{P-1} a_{R,j} h_{i,R+j}^{**}\right) = \frac{1}{\sqrt{P}} \sum_{j=1}^{P-1} a_{R,j} \bar{h}_T$ , where  $\bar{h}_T = \frac{1}{T} \sum_{t=s}^T h_t$ . The LHS of (29) can then be written as:

$$\begin{aligned} \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_{i,t}^{**} - \hat{\theta}_{i,t}) &= \left[ B_i^\dagger \frac{a_{R,0}}{\sqrt{P}} \sum_{t=s}^R (h_{i,t}^{**} - \bar{h}_T) + B_i^\dagger \frac{1}{\sqrt{P}} \sum_{j=1}^{P-1} a_{R,j} (h_{i,R+j}^{**} - \bar{h}_T) \right] \\ &\quad - B_i^\dagger \frac{a_{R,0}}{\sqrt{P}} \sum_{t=s}^R (h_t - \bar{h}_T) - B_i^\dagger \frac{1}{\sqrt{P}} \sum_{j=1}^{P-1} a_{R,j} (h_{i,R+j} - \bar{h}_T) + o_P^*(1), \quad \text{Pr } -P. \end{aligned} \quad (30)$$

The first term in square brackets on the RHS of (30) has the same limiting distribution as  $\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_{i,t}^{**} - \theta_i^*)$ , conditional on sample, while the remaining two terms on the RHS of (30) constitute the location bias term. It is then possible to construct a bootstrap a statistic that offsets the bias term. Consider,

$$\begin{aligned} \Psi_{R,P}^{**} &= \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_{i,t}^{**} - \hat{\theta}_{i,t}) + \left( -\frac{1}{P} \sum_{t=s}^P \nabla_{\theta_i}^2 q_i(y_t, Z^{t-1}, \hat{\theta}_{i,P-1}) \right)^{-1} \\ &\quad \times \left( B_i^\dagger \frac{a_{R,0}}{\sqrt{P}} \sum_{t=s}^R \left( \nabla_{\theta_i} q_i(y_t, Z^{t-1}, \hat{\theta}_{i,P-1}) - \frac{1}{T} \sum_{j=1}^T \nabla_{\theta_i} q_i(y_j, Z^{j-1}, \hat{\theta}_{i,P-1}) \right) \right. \\ &\quad \left. + \frac{1}{\sqrt{P}} \sum_{j=1}^{P-1} a_{R,j} \left( \nabla_{\theta_i} q_i(y_{R+j}, Z^{R+j-1}, \hat{\theta}_{i,P-1}) - \frac{1}{T} \sum_{j=1}^T \nabla_{\theta_i} q_i(y_j, Z^{j-1}, \hat{\theta}_{i,P-1}) \right) \right). \end{aligned} \quad (31)$$

Now,  $\Psi_{R,P}^{**} - \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_{i,t}^{**} - \hat{\theta}_{i,t})$  offsets the location bias term, and thus  $\Psi_{R,P}^{**}$  has the same limiting distribution as  $\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_{i,t} - \theta_i^*)$ , conditional on sample.<sup>14</sup>

---

<sup>14</sup>Note that only the last  $P$  observations are used to construct the estimator to be used in the correction term. In fact, if one were to use  $\hat{\theta}_{i,T-1}$  instead of  $\hat{\theta}_{i,P-1}$ , then it would follow that  $\frac{1}{T} \sum_{j=1}^T \nabla_{\theta_i} q_i(y_j, Z^{j-1}, \hat{\theta}_{i,T-1}) = 0$ , and hence the bias term could not be offset.

It follows immediately that  $\Psi_{R,P}^*$  only contains a correction term for the last  $P$  observations, while  $\Psi_{R,P}^{**}$  contains two correction terms, one for each of the first  $R$  and last  $P$  observations. In this sense,  $\Psi_{R,P}^*$  may be considered “better” than  $\Psi_{R,P}^{**}$ . However, a comparison of the two statistics deserves future research.

### 3.4.3 $V_{1P,J}$ and $V_{2P,J}$ Bootstrap Statistics Under Recursive Estimation

One can apply the results above to provide a bootstrap statistic for the case of the recursive estimation scheme. Define,

$$V_{1P,rec}^* = \sup_{r \in [0,1]} |V_{1P,rec}^*(r)|,$$

where

$$\begin{aligned} V_{1P,rec}^*(r) &= \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( \mathbb{1}\{F(y_{t+1}^*|Z^{*,t}, \hat{\theta}_t^*) \leq r\} - \mathbb{1}\{F(y_{t+1}|Z^t, \hat{\theta}_t) \leq r\} \right) \\ &\quad + \left( \Psi_{R,P}^* - \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_t^* - \hat{\theta}_t) \right). \end{aligned}$$

Also define,

$$V_{2P,rec}^* = \sup_{u \times v \in U \times V} V_{2P,rec}^*(u, v)$$

where

$$\begin{aligned} V_{2P,rec}^*(u, v) &= \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( (\mathbb{1}\{y_{t+1}^* \leq u\} - F(u|Z^{*,t}, \hat{\theta}_t^*)) \mathbb{1}\{Z^{*,t} \leq v\} - (\mathbb{1}\{y_{t+1} \leq u\} - F(u|Z^t, \hat{\theta}_t)) \mathbb{1}\{Z^t \leq v\} \right) \\ &\quad + \left( \Psi_{R,P}^* - \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_t^* - \hat{\theta}_t) \right) \end{aligned}$$

Note that versions based on the alternative (full sample) resampling procedure, can be constructed in an analogous manner, by replacing  $\hat{\theta}_t^*$  with  $\hat{\theta}_t^{**}$  and  $\Psi_{R,P}^*$  with  $\Psi_{R,P}^{**}$ . We have:

**Proposition 3.7:** Let **CS1**, **CS2(i)–(ii)** and **CS3** hold. Also, assume that as  $P, R \rightarrow \infty$ ,  $P/R \rightarrow \pi$ ,  $0 < \pi < \infty$ ,  $l_1, l_2 \rightarrow \infty$ , and that  $\frac{l_2}{P^{1/4}} \rightarrow 0$  and  $\frac{l_1}{R^{1/4}} \rightarrow 0$ . Then, as  $P$  and  $R \rightarrow \infty$ ,

$$\begin{aligned} P \left( \omega : \sup_{x \in \Re} \left| P^* [V_{1P,rec}^*(\omega) \leq u] - P \left[ \sup_{r \in [0,1]} \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( \mathbb{1}\{F(y_{t+1}|Z^t, \hat{\theta}_t) \leq r\} - E(\mathbb{1}\{F(y_{t+1}|Z^t, \theta^\dagger) \leq r\}) \right) \leq x \right] \right| > \varepsilon \right) \\ \rightarrow 0. \end{aligned}$$

**Proof:** See Appendix.

**Proposition 3.8:** Let **CS1**, **CS2(iii)–(iv)** and **CS3** hold. Also, assume that as  $P, R \rightarrow \infty$ ,  $P/R \rightarrow \pi$ ,

$0 < \pi < \infty$ ,  $l_1, l_2 \rightarrow \infty$ , and that  $\frac{l_2}{P^{1/4}} \rightarrow 0$  and  $\frac{l_1}{R^{1/4}} \rightarrow 0$ . Then, as  $P$  and  $R \rightarrow \infty$ ,

$$\begin{aligned} & P \left( \omega : \sup_{x \in \Re} |P^*[V_{2P,rec}^*(\omega) \leq x] \right. \\ & \quad \left. P \left[ \sup_{u \times v \in U \times V} \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} ((1\{y_{t+1} \leq u\} - F(u|Z^t, \hat{\theta}_t))1\{Z^t \leq v\} \right. \right. \\ & \quad \left. \left. - E((1\{y_{t+1} \leq u\} - F(u|Z^t, \theta^\dagger))1\{Z^t \leq v\})) \leq x \right] > \varepsilon \right) \\ & \rightarrow 0 \end{aligned}$$

**Proof:** See Appendix.

The same remarks given below Theorems 2.5 and 2.6 apply here.

### 3.5 Bootstrap Critical for the $V_{1P,J}$ and $V_{2P,J}$ Tests Under Rolling Estimation

In the rolling estimation scheme, observations in the middle of the sample are used more frequently than observation at either the beginning or the end of the sample. As in the recursive case, this introduces a location bias to the usual block bootstrap, as under standard resampling with replacement, any block from the original sample has the same probability of being selected. Also, the bias term varies across samples and can be either positive or negative, depending on the specific sample. In the rolling estimation scheme, we need to distinguish between the case in which  $P \leq R$  and  $P > R$ . For the time being assume  $P \leq R$ , we then explain how to modify the resampling procedure for the case of  $P > R$ .

#### 3.5.1 Split Sample Rolling PEE Bootstrap

Let  $W_t = (y_t, Z^{t-1})$ , we first draw  $b_1$  overlapping blocks of length  $l_1$ ,  $b_1 l_1 = P$  from observations  $1, \dots, P$ , then we draw  $b_2$  overlapping blocks of length  $l_2$ ,  $b_2 l_2 = R - P$  from observations  $P + 1, \dots, R$ , and finally  $b_3$  overlapping blocks of length  $l_3$ ,  $b_3 l_3 = T - R - 1$  from the last  $P$  observations. The first  $P$  pseudo observations,  $W_1^*, W_2^*, \dots, W_{l-1}^*, W_P^*$ , are equal to  $W_{I_1^1}, W_{I_1^1+1}, \dots, W_{I_1^1+l_1-1}, \dots, W_{I_{b_1}^1+l_1-1}$ , where  $I_i^1, i = 1, \dots, b_1$  are independent uniform random draws on the interval  $1, \dots, P - l_1 + 1$ , the following  $R - P - 1$  observations  $W_{P+1}^*, W_{P+2}^*, \dots, W_{P+l}^*, \dots, W_{R+1}^*$ , are equal to  $W_{I_1^2}, W_{I_1^2+1}, \dots, W_{I_1^2+l_2-1}, \dots, W_{I_{b_2}^2+l_2-1}$ , where  $I_i^2, i = 1, \dots, b_2$  are independent uniform random draws from data indexed by  $P + 1, P + 2, \dots, R - l_2 - 1$ , and finally the last  $P$  observations  $W_{R+1}^*, W_{R+2}^*, \dots, W_{R+l_3}^*, \dots, W_{R+P}^*$ , are equal to  $W_{I_1^3}, W_{I_1^3+1}, \dots, W_{I_1^3+l_3-1}, \dots, W_{I_{b_3}^3+l_3-1}$ , where  $I_i^3, i = 1, \dots, b_3$  are independent uniform random draws from data indexed by  $R + 1, R + 2, \dots, R + P - l_3 - 1$ . Thus, conditional on the (entire) sample, the pseudo time series  $W_t^*, t = 1, \dots, R, R + 1, \dots, R + P$ , consists of  $b = b_1 + b_2 + b_3$  asymptotically independent, but non identically distributed blocks of length  $l_1, l_2$  and

$l_3$  respectively. The case of  $P > R$  can be treated in an analogous way, by noting that in this case we first draw  $b_1$  overlapping blocks of length  $l_1$ ,  $b_1 l_1 = R$  from observations  $1, \dots, R$ , then we draw  $b_2$  overlapping blocks of length  $l_2$ ,  $b_2 l_2 = P - R$  from observations  $R + 1, \dots, P$ , and finally  $b_3$  overlapping blocks of length  $l_3$ ,  $b_3 l_3 = T - P$  from the last  $R$  observations. Now, define the rolling bootstrap estimator as,

$$\widehat{\theta}_{t,R}^* = \arg \max_{\theta_i \in \Theta_i} \frac{1}{R} \sum_{j=t-R+1}^t \ln f(y_j^*, Z^{*,j-1}, \theta_i), R \leq t \leq T-1.$$

Further, for  $P \leq R$ , define,

$$\begin{aligned} & \Phi_{R,P,1}^* \\ &= \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\widehat{\theta}_{t,R}^* - \widehat{\theta}_{t,R}) + \left( -\frac{1}{T} \sum_{t=s}^T \nabla_\theta^2 \ln f(y_t, Z^{t-1}, \widehat{\theta}_T) \right)^{-1} \\ & \quad \times \left[ \frac{1}{\sqrt{PR}} \sum_{j=1}^P j \left( \nabla_\theta \ln f(y_j, Z^{j-1}, \widehat{\theta}_T) - \frac{1}{P} \sum_{j=1}^P \nabla_\theta \ln f(y_j, Z^{j-1}, \widehat{\theta}_T) \right) \right. \\ & \quad \left. + \frac{1}{\sqrt{PR}} \sum_{j=R+1}^{T-1} (P - (j - R)) \left( \nabla_\theta \ln f(y_j, Z^{j-1}, \widehat{\theta}_T) - \frac{1}{P} \sum_{j=R+s+1}^{T-1} \nabla_\theta \ln f(y_j, Z^{j-1}, \widehat{\theta}_T) \right) \right] \end{aligned} \quad (32)$$

and for  $P > R$ , define,

$$\begin{aligned} & \Phi_{R,P,2}^* \\ &= \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\widehat{\theta}_{t,R}^* - \widehat{\theta}_{t,R}) + \left( -\frac{1}{T} \sum_{t=s}^T \nabla_\theta^2 \ln f(y_t, Z^{t-1}, \widehat{\theta}_T) \right)^{-1} \\ & \quad \times \left[ \frac{1}{\sqrt{PR}} \sum_{j=1}^R j \left( \nabla_\theta \ln f(y_j, Z^{j-1}, \widehat{\theta}_T) - \frac{1}{R} \sum_{j=1}^R \nabla_\theta \ln f(y_j, Z^{j-1}, \widehat{\theta}_T) \right) \right. \\ & \quad \left. + \frac{1}{\sqrt{PR}} \sum_{j=P+1}^{T-1} (R - (j - P)) \left( \nabla_\theta \ln f(y_j, Z^{j-1}, \widehat{\theta}_T) - \frac{1}{R} \sum_{j=P+1}^{T-1} \nabla_\theta \ln f(y_j, Z^{j-1}, \widehat{\theta}_T) \right) \right] \end{aligned} \quad (33)$$

**Theorem 3.9 (from Proposition 2 in Corradi and Swanson (2003c)):** Let **CS1** and **CS3** hold.

(i) Assume that as  $P \rightarrow \infty$  and  $l_1 \rightarrow \infty$ ,  $l_1/P^{1/4} \rightarrow 0$ , and as  $R \rightarrow \infty$  and  $l_3 \rightarrow \infty$ ,  $l_3/P^{1/4} \rightarrow 0$ , and finally as  $R - P \rightarrow \infty$  and  $l_2 \rightarrow \infty$ ,  $l_2/(R - P)^{1/4} \rightarrow 0$ , and  $P/R \rightarrow \pi$ ,  $0 < \pi < \infty$ . Then, as  $P \rightarrow \infty$  and  $R \rightarrow \infty$ , for  $P \leq R$ ,

$$P \left( \omega : \sup_{v \in \Re^{\varrho(i)}} \left| P_{R,P}^* (\Phi_{R,P,1}^* \leq v) - P \left( \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\widehat{\theta}_{t,R} - \theta^\dagger) \leq v \right) \right| > \varepsilon \right) \rightarrow 0.$$

(ii) Assume that as  $R \rightarrow \infty$  and  $l_1 \rightarrow \infty$ , that  $l_1/R^{1/4} \rightarrow 0$ , and as  $P \rightarrow \infty$  and  $l_3 \rightarrow \infty$ ,  $l_3/R^{1/4} \rightarrow 0$ , and finally as  $P - R \rightarrow \infty$  and  $l_2 \rightarrow \infty$ ,  $l_2/(P - R)^{1/4} \rightarrow 0$ , and  $P/R \rightarrow \pi$ ,  $0 < \pi < \infty$ . Then, as  $P$  and

$R \rightarrow \infty$ , for  $P > R$ ,

$$P \left( \omega : \sup_{v \in \Re^{o(i)}} \left| P_{R,P}^* (\Phi_{R,P,2}^* \leq v) - P \left( \frac{1}{\sqrt{P}} \sum_{t=R+s}^{T-1} (\hat{\theta}_{t,R} - \theta^\dagger) \leq v \right) \right| > \varepsilon \right) \rightarrow 0,$$

where  $P_{R,P}^*$  denotes the probability law of the resampled series, conditional on the (entire) sample.

Broadly speaking, Theorem 3.9 states that for  $P \leq R$ ,  $\Phi_{R,P,1}^*$  and for  $P > R$ ,  $\Phi_{R,P,2}^{*(i)}$  has the same limiting distribution as  $\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_{t,R} - \theta^\dagger)$ , conditional on sample, and for all samples except a set with probability measure approaching zero. Note that, if  $|R - P| = o(T)$ , then the contribution of the observations in that range is asymptotically negligible. Also, note that we do not need any adjustment term for the observations between  $P$  and  $R$ , or between  $R$  and  $P$ , depending whether  $P$  is larger or smaller than  $R$ . The intuitive reason is that all observations in that range carry the same weight (i.e. are used the same number of times), and therefore the standard block bootstrap, when ‘‘applied’’ to the observations in that range, works properly.

It is worthwhile to give an intuitive explanation of why there is an adjustment term in  $\Phi_{R,P,1}^*$  (and in  $\Phi_{R,P,2}^*$ ). For notational simplicity in the current discussion, let  $h_t = \nabla_\theta \ln f(y_t, Z^{t-1}, \theta^\dagger)$  and  $h_t^* = \nabla_\theta \ln f(y_t^*, Z^{*,t-1}, \theta^\dagger)$ . Via a mean value expansion around  $\theta^\dagger$ , using arguments similar to those used in Lemma 4.1 of West and McCracken (1998), for the case of  $P \leq R$  we have,

$$\begin{aligned} & \frac{1}{\sqrt{P}} \sum_{t=R+s}^{T-1} (\hat{\theta}_{t,R} - \theta^\dagger) \\ &= B^\dagger \frac{1}{\sqrt{PR}} \left( \sum_{j=1}^P j h_{i,j} + P \sum_{j=P+1}^R h_{i,j} + \sum_{j=R+1}^{T-1} (P - (j-R)) h_j \right) + o_P(1) \end{aligned} \quad (34)$$

where it should be recalled that  $B^\dagger = \left( E \left( -\nabla_\theta^2 \ln f(y_t, Z^{t-1}, \theta_i^\dagger) \right) \right)^{-1}$ . Also,

$$\begin{aligned} & \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_{t,R}^* - \hat{\theta}_{t,R}) \\ &= A_i^\dagger \frac{1}{\sqrt{PR}} \left( \sum_{j=1}^P j (h_j^* - h_j) + P \sum_{j=P+1}^R (h_j^* - h_j) + \sum_{j=R+1}^{T-1} (P - (j-R)) (h_j^* - h_j) \right) \\ & \quad + o_P^*(1), \quad \Pr - P \end{aligned} \quad (35)$$

Now, up to a term of order  $O_P^* (l/\sqrt{P})$ ,

$$E^* \left( \frac{1}{\sqrt{PR}} \sum_{j=1}^P j h_j^* \right) = \frac{1}{\sqrt{PR}} \sum_{j=1}^P j \frac{1}{P} \sum_{j=1}^P h_j \neq \frac{1}{\sqrt{PR}} \sum_{j=1}^P j h_{i,j},$$

and similarly,

$$\begin{aligned} E^* \left( \frac{1}{\sqrt{PR}} \sum_{j=P+1}^R (P - (j + R)) h_j^* \right) &= \\ \frac{1}{\sqrt{PR}} \sum_{j=R+1}^{T-1} (P - (j - R)) \frac{1}{P} \sum_{j=R+1}^{T-1} h_j &\neq \frac{1}{\sqrt{PR}} \sum_{j=R+1}^{T-1} (P - (j - R)) h_j, \end{aligned}$$

Therefore, the expectation of the RHS in (35), computed under the bootstrap law,  $P_{R,P}^*$ , is not zero, so that we cannot expect  $\frac{1}{\sqrt{P}} \sum_{t=R+s}^{T-1} (\hat{\theta}_{t,R}^* - \hat{\theta}_{t,R})$  to converge in  $P_{R,P}^*$ -distribution to a zero mean normal. Now, rewrite (34) as,

$$\begin{aligned} & \frac{1}{\sqrt{P}} \sum_{t=R+s}^{T-1} (\hat{\theta}_t^* - \hat{\theta}_t) \\ = & B^\dagger \left[ \frac{1}{\sqrt{PR}} \sum_{j=1}^P j (h_j^* - \bar{h}_P) + \frac{\sqrt{P}}{R} \sum_{j=P+1}^R (h_{R+j}^* - \bar{h}_{R-P}) \right. \\ & \left. + \frac{1}{\sqrt{PR}} \sum_{j=R+1}^{T-1} (P - (j - R)) (h_j^* - \bar{h}_{T-R}) \right] \\ & - A_i^\dagger \left[ \frac{1}{\sqrt{PR}} \sum_{j=1}^P j (h_j - \bar{h}_P) + \frac{1}{\sqrt{PR}} \sum_{j=R+1}^{T-1} (P - (j - R)) (h_j - \bar{h}_{T-R}) \right] \\ & + o_P^*(1), \quad \text{Pr } -P, \end{aligned} \tag{36}$$

where  $\bar{h}_P$ ,  $\bar{h}_{R-P}$ , and  $\bar{h}_{T-R}$  are the sample means constructed observations from 1 to  $P$ , observations between  $P$  and  $R$  and from the last  $P$  observations. The first term on the RHS of (36) mimics the limiting distribution of  $\frac{1}{\sqrt{P}} \sum_{t=R+s}^{T-1} (\hat{\theta}_{t,R}^* - \theta^*)$ , conditional on sample. On the other hand, the second term on the RHS is  $O(1)$ , conditional on sample, and for all samples except a set with probability measure approaching zero. Therefore, the second term in (36) can be interpreted as a location bias term of the standard block bootstrap. Such bias can be either positive or negative across different samples. Also, the difference between the second term on the RHS of (52) and the second term on the RHS of (36) vanishes asymptotically. Therefore, the adjustment term completely offsets the second term on the RHS of (36), as  $R$  and  $P$  go to infinity.

In the above discussion, we consider the case in which all parameters are jointly estimated. However, it is quite customary to first estimate conditional mean parameters via OLS or NLS and subsequently estimate the error variance using residuals. Results analogous to those discussed above follow in this case, and details are given in Corradi and Swanson (2003c).

### 3.5.2 Full Sample Rolling PEE Bootstrap

Suppose we instead resample  $P + R$  observations from the entire sample. Let let  $W_t = (y_t, Z^{t-1})$ , and draw  $b$  overlapping blocks of length  $l$ , where  $bl = T$ . The resampled observations,  $W_1^{**}, W_2^{**}, \dots, W_l^{**}, \dots, W_T^{**}$ , are equal to  $W_{I_1}, W_{I_1+1}, \dots, W_{I_b+l-1}, \dots, W_{I_b+1}$ , where  $I_i, i = 1, \dots, b$  are independent uniform random draws on the interval  $1, \dots, T - l + 1$ . Let  $\hat{\theta}_{t,R}^{**}$  be defined as in (20), but using  $W_t^{**}$  instead of  $W_t^*$ . Also, let  $h_t^{**} = \nabla_\theta q(y_t^{**}, Z^{**}, t-1, \theta^\dagger)$ . For sake of brevity, we consider only the case of  $P < R$ . Now, from (35), we have

$$\begin{aligned} & \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_{t,R}^{**} - \hat{\theta}_{t,R}) \\ &= A_i^\dagger \frac{1}{\sqrt{PR}} \left( \sum_{j=1}^P j(h_j^* - h_j) + P \sum_{j=P+1}^R (h_j^* - h_j) + \sum_{j=R+1}^{T-1} (P - (j-R))(h_j^* - h_j) \right) \\ & \quad + o_P^*(1), \quad \text{Pr } P \end{aligned} \tag{37}$$

Now, up to a term of order  $O_P^*(l/\sqrt{P})$ ,

$$\begin{aligned} E^* \left( \frac{1}{\sqrt{PR}} \sum_{j=1}^P j h_{i,j}^* \right) &= \frac{1}{\sqrt{PR}} \sum_{j=1}^P (j-s) \frac{1}{T} \sum_{j=1}^T h_{i,j} \neq \frac{1}{\sqrt{PR}} \sum_{j=1}^P (j-s) h_{i,j}, \\ E^* \left( \frac{\sqrt{P}}{R} \sum_{j=1}^P h_j^* \right) &= \frac{P^{3/2}}{TR} \sum_{j=1}^T h_j \neq \frac{1}{\sqrt{PR}} \sum_{j=1}^P j h_j, \end{aligned}$$

and similarly,

$$\begin{aligned} E^* \left( \frac{1}{\sqrt{PR}} \sum_{j=R+1}^{T-1} (P - (j+R)) h_j^* \right) &= \\ \frac{1}{\sqrt{PR}} \sum_{j=R+1}^{T-1} (P - (j+R)) \frac{1}{T} \sum_{j=1}^{T-1} h_j &\neq \frac{1}{\sqrt{PR}} \sum_{j=R+1}^{T-1} (P - (j+R)) h_j, \end{aligned}$$

Hereafter, let  $\bar{h}_T = \frac{1}{T} \sum_{j=1}^T h_j$ . Now,

$$\begin{aligned} & \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_{t,R}^{**} - \hat{\theta}_{t,R}) \\ &= A_i^\dagger \frac{1}{\sqrt{PR}} \left( \sum_{j=1}^P j(h_j^* - \bar{h}_T) + P \sum_{j=P+1}^R (h_j^* - \bar{h}_T) + \sum_{j=R+1}^{T-1} (P + (j-R))(h_j^* - \bar{h}_T) \right) \\ & \quad - A_i^\dagger \frac{1}{\sqrt{PR}} \left( \sum_{j=1}^P j(h_j - \bar{h}_T) + P \sum_{j=P+1}^R (h_j - \bar{h}_T) + \sum_{j=R+1}^{T-1} (P - (j-R))(h_j - \bar{h}_T) \right) \\ & \quad + o_P^*(1), \quad \text{Pr } P \end{aligned} \tag{38}$$

Note that the first line on the RHS of (38) has the same limiting distribution as  $\frac{1}{\sqrt{P}} \sum_{t=R+s}^{T-1} (\hat{\theta}_{t,R} - \theta^\dagger)$ , conditional on the sample and for all sample but a set of probability measure approaching zero. On the other hand, the last line on the RHS of (38) is a location bias term, which is either positive or negative across different samples. For convenience, define  $\widehat{B}_T = \left( -\frac{1}{T} \sum_{t=1}^T \nabla_\theta^2 \ln f(y_t, Z^{t-1}, \widehat{\theta}_P) \right)^{-1}$ ,  $\widehat{h}_t = \nabla_\theta \ln f(y_t, Z^{t-1}, \widehat{\theta}_P)$  and  $\widehat{h} = \frac{1}{T} \sum_{t=1}^T \nabla_\theta \ln f(y_t, Z^{t-1}, \widehat{\theta}_P)$ . Consider, for the case of  $P \leq R$ ,

$$\begin{aligned} \Phi_{R,P}^{**} &= \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\widehat{\theta}_t^{**} - \widehat{\theta}_t) + \\ &+ \widehat{A}_{i,T} \frac{1}{\sqrt{PR}} \left( \sum_{j=1}^P j(\widehat{h}_{i,j} - \widehat{h}_{i,T}) + P \sum_{j=P+1}^R (\widehat{h}_j - \widehat{h}_T) \right) + \\ &+ \sum_{j=R+1}^{T-1} (P - (j-R))(\widehat{h}_j - \widehat{h}_T) \end{aligned} \quad (39)$$

### 3.5.3 $V_{1P,J}$ and $V_{2P,J}$ Bootstrap Statistics Under Rolling Estimation

We now outline the asymptotic behavior of the out of sample version of the statistics in Corradi and Swanson (2003a) for the case in which parameters are estimated using the rolling estimation scheme. Assuming,  $P \leq R$ , define,

$$V_{1P,rol}^* = \sup_{r \in [0,1]} |V_{1P,rol}(r)|,$$

where

$$\begin{aligned} V_{1P,rol}^*(r) &= \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( 1\{F(y_{t+1}^* | Z^{*,t}, \widehat{\theta}_{t,R}^*) \leq r\} - 1\{F(y_{t+1} | Z^t, \widehat{\theta}_{t,R}) \leq r\} \right) \\ &+ \left( \Phi_{R,P,1}^* - \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\widehat{\theta}_t^* - \widehat{\theta}_t) \right). \end{aligned}$$

Also define,

$$V_{2P,rol}^* = \sup_{u \times v \in U \times V} V_{2P,rol}^*(u, v)$$

where

$$\begin{aligned} V_{2P,rol}^*(u, v) &= \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( (1\{y_{t+1}^* \leq u\} - F(u | Z^{*,t}, \widehat{\theta}_t^*)) 1\{Z^{*,t} \leq v\} - (1\{y_{t+1} \leq u\} - F(u | Z^t, \widehat{\theta}_t)) 1\{Z^t \leq v\} \right) . \\ &+ \left( \Psi_{R,P,1}^* - \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\widehat{\theta}_t^* - \widehat{\theta}_t) \right) \end{aligned}$$

Note that for the case of  $P > R$ , it suffices to replace  $\Psi_{R,P,1}^*$  with  $\Psi_{R,P,2}^*$ ; also versions based on the alternative (full sample) resampling procedure, can be constructed in an analogous manner, by replacing  $\widehat{\theta}_t^*$  with  $\widehat{\theta}_t^{**}$  and  $\Psi_{R,P}^*$  with  $\Psi_{R,P}^{**}$ . The following result pertains given the above setup.

**Proposition 3.10:** Let **CS1**, **CS2(i)–(ii)** and **CS3** hold. Also, assume that as  $P, R \rightarrow \infty$ ,  $P/R \rightarrow \pi$ ,  $0 < \pi < \infty$ ,  $l_1, l_2 \rightarrow \infty$ , and that  $\frac{l_2}{P^{1/4}} \rightarrow 0$  and  $\frac{l_1}{R^{1/4}} \rightarrow 0$ . Then, as  $P$  and  $R \rightarrow \infty$  and  $P/R \rightarrow \pi$ ,  $0 < \pi < \infty$ ,

$$P \left( \omega : \sup_{x \in \Re} \left| P^* [V_{1P,rol}^*(\omega) \leq u] - P \left[ \sup_{r \in [0,1]} \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( 1\{F(y_{t+1}|Z^t, \hat{\theta}_{t,R}) \leq r\} - E \left( 1\{F(y_{t+1}|Z^t, \theta^\dagger) \leq r\} \right) \right) \leq x \right] \right| > \varepsilon \right) \quad (40)$$

$$\rightarrow 0$$

**Proof:** See Appendix.

**Proposition 3.11:** Let **CS1**, **CS2(iii)–(iv)** and **CS3** hold. Also, assume that as  $P, R \rightarrow \infty$ ,  $P/R \rightarrow \pi$ ,  $0 < \pi < \infty$ ,  $l_1, l_2 \rightarrow \infty$ , and that  $\frac{l_2}{P^{1/4}} \rightarrow 0$  and  $\frac{l_1}{R^{1/4}} \rightarrow 0$ . Then, as  $P$  and  $R \rightarrow \infty$ , and  $P/R \rightarrow \pi$ ,  $0 < \pi < \infty$ ,

$$\begin{aligned} & P \left( \omega : \sup_{x \in \Re} \left| P^* [V_{2P,rol}^*(\omega) \leq x] \right. \right. \\ & \quad \left. \left. - E \left[ \sup_{u \times v \in U \times V} \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} ((1\{y_{t+1} \leq u\} - F(u|Z^t, \hat{\theta}_{t,R})) 1\{Z^t \leq v\} \right. \right. \\ & \quad \left. \left. - E((1\{y_{t+1} \leq u\} - F(u|Z^t, \theta^\dagger)) 1\{Z^t \leq v\})) \leq x \right] \right| > \varepsilon \right) \\ & \rightarrow 0 \end{aligned}$$

**Proof:** See Appendix.

The same remarks given below Theorems 2.5 and 2.6 apply here.

## Part III: Evaluation of (Multiple) Misspecified Predictive Models

### 4 Pointwise Comparison of (Multiple) Misspecified Predictive Models

In the previous two sections we discussed several in sample and out of sample tests for the null of either correct dynamic specification of the conditional distribution or for the null of correct conditional distribution for given information set. Needless to say, the correct (either dynamically, or for a given information set) conditional distribution is the best predictive density. However, it is often sensible to account for the fact that all models may be approximations, and so may be misspecified. The literature on point forecast evaluation

does indeed acknowledge that the objective of interest is often to choose a model which provides the best (loss function specific) out of sample predictions, from amongst a set of potentially misspecified models, and not just from amongst models that may only be dynamically misspecified, as is the case with some of the tests discussed above. In this section we outline several popular tests for comparing the relative out of sample accuracy of misspecified models in the case of point forecasts. We shall distinguish among three main group of tests: (i) tests for comparing two nonnested models, (ii) tests for comparing two (or more) nested models; and (iii) tests for comparing multiple models, where at least one model is non-nested. In the next section, we broaden the scope by considering tests for comparing misspecified predictive density models.

#### 4.1 Comparison of Two Nonnested Models: Diebold and Mariano Test

Diebold and Mariano (DM: 1995) propose a test for the null hypothesis of equal predictive ability that is based part on the pairwise model comparison test discussed in Granger and Newbold (1986). The Diebold and Mariano test allows for nondifferentiable loss functions, but does not explicitly account for parameter estimation error, instead relying on the assumption that the in-sample estimation period is growing more quickly than the out-of-sample prediction period, so that parameter estimation error vanishes asymptotically. West (1996) takes the more general approach of explicitly allowing for parameter estimation error, although at the cost of assuming that the loss function used is differentiable. Let  $u_{0,t+h}$  and  $u_{1,t+h}$  be the  $h$ -step ahead prediction error associated with predictions of  $y_{t+h}$ , using information available up to time  $t$ . For example, for  $h = 1$ ,  $u_{0,t+1} = y_{t+1} - \kappa_0(Z_0^{t-1}, \theta_0^\dagger)$ , and  $u_{1,t+1} = y_{t+1} - \kappa_1(Z_1^{t-1}, \theta_1^\dagger)$ , where  $Z_0^{t-1}$  and  $Z_1^{t-1}$  contain past values of  $y_t$  and possibly other conditioning variables. Assume that the two models be nonnested (i.e.  $Z_0^{t-1}$  not a subset of  $Z_1^{t-1}$  -and vice-versa- and/or  $\kappa_1 \neq \kappa_0$ ). As lucidly pointed out by Granger and Pesaran (2000), when comparing misspecified models, the ranking of models based on their predictive accuracy depends on the loss function used. Hereafter, denote the loss function as  $g$ , and as usual let  $T = R + P$ , where only the last  $P$  observations are used for model evaluation. Under the assumption that  $u_{0,t}$  and  $u_{1,t}$  are strictly stationary, the null hypothesis of equal predictive accuracy is specified as:

$$H_0 : E(g(u_{0,t}) - g(u_{1t})) = 0$$

and

$$H_A : E(g(u_{0,t}) - g(u_{1t})) \neq 0$$

In practice, we do not observe  $u_{0,t+1}$  and  $u_{1,t+1}$ , but only  $\hat{u}_{0,t+1}$  and  $\hat{u}_{1,t+1}$ , where  $\hat{u}_{0,t+1} = y_{t+1} - \kappa_0(Z_0^t, \hat{\theta}_{0,t})$ , and where  $\hat{\theta}_{0,t}$  is an estimator constructed using observations from 1 up to  $t$ ,  $t \geq R$ , in the recursive estimation

case, and between  $t - R + 1$  and  $t$  in the rolling case. For brevity, in this subsection we just consider the recursive scheme. However, the rolling scheme can be treated in an analogous manner. Of crucial importance is the loss function used for estimation. In fact, as we shall show below if we use the same loss function for estimation and model evaluation, the contribution of parameter estimation error is asymptotically negligible, regardless the limit of the ratio  $P/R$  as  $T \rightarrow \infty$ . Here, for  $i = 0, 1$

$$\hat{\theta}_{i,t} = \arg \min_{\theta_i \in \Theta_i} \frac{1}{t} \sum_{j=1}^t q(y_j - \kappa_i(Z_i^{\tau-1}, \theta_i)), \quad t \geq R$$

In the sequel, we rely on the assumption that  $g$  is continuously differentiable. The case of non-differentiable loss functions is treated by McCracken (2000,2003). Now,

$$\begin{aligned} \frac{1}{\sqrt{P}} \sum_{t=R}^{T-h} g(\hat{u}_{i,t+1}) &= \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} g(u_{i,t+1}) + \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \nabla g(\bar{u}_{i,t+1}) (\hat{\theta}_{i,t} - \theta_i^\dagger) \\ &= \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} g(u_{i,t+1}) + E(\nabla g(u_{i,t+1})) \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\hat{\theta}_{i,t} - \theta_i^\dagger) + o_P(1). \end{aligned} \quad (41)$$

It is immediate to see that if  $g = q$  (i.e. the same loss is used for estimation and model evaluation), then  $E(\nabla g(u_{i,t+1})) = 0$  because of the first order conditions. Of course, another case in which the second term on the RHS of (41) vanishes is when  $P/R \rightarrow 0$  (these are the cases DM consider). The limiting distribution of the RHS in (41) is given in Section 3.1. The Diebold and Mariano test is

$$DM_P = \frac{1}{\sqrt{P}} \frac{1}{\hat{\sigma}_P} \sum_{t=R}^{T-1} (g(\hat{u}_{0,t+1}) - g(\hat{u}_{1,t+1})),$$

where

$$\begin{aligned} &\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (g(\hat{u}_{0,t+1}) - g(\hat{u}_{1,t+1})) \\ &\xrightarrow{d} N(0, S_{gg} + 2\Pi F_0' B_0 S_{h_0 h_0} B_0 F_0 \\ &\quad + 2\Pi F_1' B_1 S_{h_1 h_1} B_1 F_1 - \Pi(S_{g h_0}' B_0 F_0 + F_0' B_0 S_{g h_0}) \\ &\quad - 2\Pi(F_1' B_1 S_{h_1 h_0} B_0 F_0 + F_0' B_0 S_{h_0 h_1} B_1 F_1) \\ &\quad + \Pi(S_{g h_1}' B_1 F_1 + F_1' B_1 S_{g h_1})), \end{aligned}$$

with

$$\begin{aligned} \hat{\sigma}_P^2 &= \hat{S}_{gg} + 2\Pi \hat{F}_0' \hat{B}_0 \hat{S}_{h_0 h_0} + 2\Pi \hat{F}_1' \hat{B}_1 \hat{S}_{h_1 h_1} \hat{B}_1 \hat{F}_1 \\ &\quad - 2\Pi(\hat{F}_1' \hat{B}_1 \hat{S}_{h_1 h_0} \hat{B}_0 \hat{F}_0 + \hat{F}_0' \hat{B}_0 \hat{S}_{h_0 h_1} \hat{B}_1 \hat{F}_1) + \Pi(\hat{S}_{g h_1}' \hat{B}_1 \hat{F}_1 + \hat{F}_1' \hat{B}_1 \hat{S}_{g h_1}), \end{aligned}$$

where for  $i, l = 0, 1$ ,  $\Pi = \Pi = 1 - \pi^{-1} \ln(1 + \pi)$ , and  $q_t(\hat{\theta}_{i,t}) = q(y_t - \kappa_i(Z_i^{t-1}, \hat{\theta}_{i,t}))$ ,

$$\begin{aligned}\widehat{S}_{h_i h_l} &= \frac{1}{P} \sum_{\tau=-l_P}^{l_P} w_\tau \sum_{t=R+l_P}^{T-l_P} \nabla_\theta q_t(\hat{\theta}_{i,t}) \nabla_\theta q_{t+\tau}(\hat{\theta}_{l,t})' \\ \widehat{S}_{fh_i} &= \frac{1}{P} \sum_{\tau=-l_P}^{l_P} w_\tau \sum_{t=R+l_P}^{T-l_P} \\ &\quad \left( (g(\hat{u}_{0,t}) - g(\hat{u}_{1,t})) - \frac{1}{P} \sum_{t=R}^{T-1} (g(\hat{u}_{0,t+1}) - g(\hat{u}_{1,t+1})) \right) \\ &\quad \times \nabla_\beta q_{t+\tau}(\hat{\theta}_{i,t})' \\ \widehat{S}_{gg} &= \frac{1}{P} \sum_{\tau=-l_P}^{l_P} w_\tau \sum_{t=R+l_P}^{T-l_P} \\ &\quad \left( g(\hat{u}_{0,t}) - g(\hat{u}_{1,t}) - \frac{1}{P} \sum_{t=R}^{T-1} (g(\hat{u}_{0,t+1}) - g(\hat{u}_{1,t+1})) \right) \\ &\quad \left( g(\hat{u}_{0,t+\tau}) - g(\hat{u}_{1,t+\tau}) - \frac{1}{P} \sum_{t=R}^{T-1} (g(\hat{u}_{0,t+1}) - g(\hat{u}_{1,t+1})) \right)\end{aligned}$$

with  $w = 1 - \left(\frac{\tau}{l_P+1}\right)$ , and where

$$\widehat{F}_i = \frac{1}{P} \sum_{t=R}^{T-1} \nabla_{\theta_i} g(\hat{u}_{i,t+1}), \quad \widehat{B}_i = \left( -\frac{1}{P} \sum_{t=R}^{T-1} \nabla_{\theta_i}^2 q(\hat{\theta}_{i,t}) \right)^{-1}$$

**Proposition 4.1 (from Theorem 4.1 in West (1996)):** Let **W1-W2** hold. Also, assume that  $g$  is continuously differentiable, then, if as  $P \rightarrow \infty$ ,  $l_p \rightarrow \infty$  and  $l_P/P^{1/4} \rightarrow 0$ , then as  $P, R \rightarrow \infty$ , under  $H_0$ ,  $DM_P \xrightarrow{d} N(0, 1)$  and under  $H_A$ ,  $\Pr(P^{-1/2} |DM_P| > \varepsilon) \rightarrow 1$ , for any  $\varepsilon > 0$ .

Recall that it is immediate to see that if either  $g = q$  or  $P/R \rightarrow 0$ , then the estimator of the long-run variance collapses to  $\widehat{\sigma}_P^2 = \widehat{S}_{gg}$ . The proposition is valid for the case of short-memory series. Corradi, Swanson and Olivetti (2001) consider DM tests in the context of cointegrated series, and Rossi (2003) in the context of processes with roots local to unity.

The proposition above has been stated in terms of one-step ahead prediction errors. All results carry over to the case of  $h > 1$ . However, in the multistep ahead case, one needs to decide whether to compute “direct”  $h$ -step ahead forecast errors (i.e.  $\hat{u}_{i,t+h} = y_{t+h} - \kappa_i(Z_i^{t-h}, \hat{\theta}_{i,t})$ ) or to compute iterated  $h$ -ahead forecast errors (i.e. first predict  $y_{t+1}$  using observations up to time  $t$ , and then use this predicted value in order to predict  $y_{t+2}$ , and so on). Within the context of VAR models, Marcellino, Stock and Watson (2004) conduct an extensive and careful Monte Carlo study in order to examine the properties of these direct and indirect approaches to prediction.

Finally, note that when the two models are nested, so that  $u_{0,t} = u_{1,t}$  under  $H_0$ , both the numerator of the  $DM_P$  statistic and  $\hat{\sigma}_P$  approach zero in probability at the same rate, if  $P/R \rightarrow 0$ , so that the  $DM_P$  statistic no longer has a normal limiting distribution under the null. Comparison of nested models is the subject of the next subsection.

## 4.2 Comparison of Two Nested Models

In several instances we may be interested in comparing nested models, such as when forming out of sample Granger causality tests. Also, in the empirical international finance literature, an extensively studied issue concerns comparing the relative accuracy of models driven by fundamentals against random walk models. Since the seminal paper by Meese and Rogoff (1983), who find that no economic models can beat a random walk in terms of their ability to predict exchange rates, several papers have tried to challenge that view, a partial list of which includes Mark (1995), Kilian (1999a), Clarida, Sarno and Taylor (2003), Kilian and Taylor (2003) and Rossi (2003), Clark and West (2004), and McCracken and Sapp (2004). Indeed, the debate about predictability of exchange rates was one of the driving force behind the literature on out of sample comparison of nested models.

### 4.2.1 Clark and McCracken Tests

Within the context of nested linear models, Clark and McCracken (CMa: 2001) propose some easy to implement tests, under the assumption of martingale difference prediction errors (these tests thus rule out the possibility of dynamic misspecification under the null model). Such tests are thus tailored for the case of one-step ahead prediction. This is because  $h$ -step ahead prediction errors follow an  $MA(h-1)$  process. For the case where  $h > 1$ , Clark and McCracken (CMb: 2003) propose a different set tests. We begin by outlining the CMa tests.

Consider the following two nested models. The restricted model is

$$y_t = \sum_{j=1}^q \beta_j y_{t-j} + \epsilon_t \quad (42)$$

and the unrestricted model is

$$y_t = \sum_{j=1}^q \beta_j y_{t-j} + \sum_{j=1}^k \alpha_j x_{t-j} + u_t \quad (43)$$

The null and the alternative hypotheses are formulated as:

$$H_0 : E(\epsilon_t^2) - E(u_t^2) = 0$$

$$H_A : E(\epsilon_t^2) - E(u_t^2) > 0,$$

so that it is implicitly assumed that the smaller model cannot outperform the larger. This is actually the case when the loss function is quadratic and when parameters are estimated by LS, which is the case considered by CMa. Note that under the null hypothesis,  $u_t = \epsilon_t$ , and so DM tests are not applicable in the current context. We use the following assumptions in the sequel of this section.

**CM1:**  $(y_t, x_t)$  are strictly stationary, strong mixing processes, with size  $\frac{-4(4+\delta)}{\delta}$ , for some  $\delta > 0$ , and  $E(y_t)^8 < \infty, E(x_t)^8$ .

**CM2:** Let  $z_t = (y_{t-1}, \dots, y_{t-q}, x_{t-1}, \dots, x_{t-q})$  and  $E(z_t u_t | \mathfrak{I}_{t-1}) = 0$ , where  $\mathfrak{I}_{t-1}$  contains all the information at time  $t-1$  generated by all the past of  $x_t$  and  $y_t$ . Also,  $E(u_t^2 | \mathfrak{I}_{t-1}) = \sigma_u^2$ .

Note that **CM2** requires that the larger model is dynamically correctly specified, and requires  $u_t$  to be conditionally homoskedastic. The three different tests proposed by CMa are

$$ENC - T = (P - 1)^{1/2} \frac{\bar{c}}{(P^{-1} \sum_{t=R}^{T-1} (c_{t+1} - \bar{c}))^{1/2}},$$

where  $c_{t+1} = \hat{\epsilon}_{t+1}(\hat{\epsilon}_{t+1} - \hat{u}_{t+1})$ ,  $\bar{c} = P^{-1} \sum_{t=R}^{T-1} c_{t+1}$ , and where  $\hat{\epsilon}_{t+1}$  and  $\hat{u}_{t+1}$  are residuals from the LS estimation. Additionally,

$$ENC - REG = (P - 1)^{1/2} \frac{P^{-1} \sum_{t=R}^{T-1} (\hat{\epsilon}_{t+1}(\hat{\epsilon}_{t+1} - \hat{u}_{t+1}))}{(P^{-1} \sum_{t=R}^{T-1} (\hat{\epsilon}_{t+1} - \hat{u}_{t+1})^2 P^{-1} \sum_{t=R}^{T-1} \hat{\epsilon}_{t+1}^2 - \bar{c}^2)^{1/2}},$$

and

$$ENC - NEW = P \frac{\bar{c}}{P^{-1} \sum_{t=1}^{T-1} \hat{u}_{t+1}^2}$$

**Proposition 4.2 (from Theorems 3.1, 3.2, 3.3 in CMa):** Let **CM1-CM2** hold. Then under the null,

(i) If as  $T \rightarrow \infty$ ,  $P/R \rightarrow \pi > 0$ , then  $ENC - T$  and  $ENC - REG$  converge in distribution to  $\Gamma_1/\Gamma_2$  where  $\Gamma_1 = \int_{(1+\pi)^{-1}}^1 s^{-1} W'(s) dW(s)$  and  $\Gamma_2 = \int_{(1+\pi)^{-1}}^1 s^{-2} W'(s) W(s) ds$ . Here,  $W(s)$  is a standard  $k$ -dimensional Brownian motion (note that  $k$  is the number of restrictions or the number of extra regressors in the larger model). Also,  $ENC - NEW$  converges in distribution to  $\Gamma_1$ , and

(ii) If as  $T \rightarrow \infty$ ,  $P/R \rightarrow \pi = 0$ , then  $ENC - T$  and  $ENC - REG$  converge in distribution to  $N(0, 1)$ , and  $ENC - NEW$  converges to 0 in probability.

Thus, for  $\pi > 0$  all three tests have non-standard limiting distributions, although the distributions are nuisance parameter free. Critical values for these statistics under  $\pi > 0$  have been tabulated by CMa for different values of  $k$  and  $\pi$ .

It is immediate to see that **CM2** is violated in the case of multiple step ahead prediction errors. For the case of  $h > 1$ , CMb provide modified versions of the above tests in order to allow for MA( $h-1$ ) errors. Their

modification essentially consists of using a robust covariance matrix estimator in the context of the above tests.<sup>15</sup> Their new version of the  $ENC - T$  test is

$$ENC - T' = (P - h + 1)^{1/2} \frac{\frac{1}{P-h+1} \sum_{t=R}^{T-h} \hat{c}_{t+h}}{\frac{1}{P-h+1} \sum_{j=-\bar{j}}^{\bar{j}} \sum_{t=R+j}^{T-h} K(\frac{j}{M}) (\hat{c}_{t+h} - \bar{c})(\hat{c}_{t+h-j} - \bar{c})}, \quad (44)$$

where  $\hat{c}_{t+h} = \hat{\epsilon}_{t+h} (\hat{\epsilon}_{t+h} - \hat{u}_{t+h})$ ,  $\bar{c} = \frac{1}{P-h+1} \sum_{t=R}^{T-h} \hat{c}_{t+h}$ ,  $K(\cdot)$  is a kernel (such as the Bartlett kernel), and  $0 \leq K(\frac{j}{M}) \leq 1$ , with  $K(0) = 1$ , and  $M = o(P^{1/2})$ . Note that  $\bar{j}$  does not grow with the sample size. Therefore, the denominator in  $ENC - T'$  is a consistent estimator of the long run variance only when  $E(c_t c_{t+|k|}) = 0$  for all  $|k| > h$  (see Assumption A3 in CMb). Thus, the statistic takes into account the moving average structure of the prediction errors, but still does not allow for dynamic misspecification under the null. Another statistic suggested by CMb is a rescaled version of the Diebold Mariano statistic. Namely

$$MSE - T = (P - h + 1)^{1/2} \frac{\frac{1}{P-h+1} \sum_{t=R}^{T-h} \hat{d}_{t+h}}{\frac{1}{P-h+1} \sum_{j=-\bar{j}}^{\bar{j}} \sum_{t=R+j}^{T-h} K(\frac{j}{M}) (\hat{d}_{t+h} - \bar{d})(\hat{d}_{t+h-j} - \bar{d})},$$

where  $\hat{d}_{t+h} = \hat{\epsilon}_{t+h}^2 - \hat{u}_{t+h}^2$ , and  $\bar{d} = \frac{1}{P-h+1} \sum_{t=R}^{T-h} \hat{d}_{t+h}$ .

The limiting distributions of the  $ENC - T'$  and  $MSE - T$  statistics are given in Theorems 3.1 and 3.2 in CMb, and for  $h > 1$  contain nuisance parameters so their critical values cannot be directly tabulated. CMb suggest using a modified version of the bootstrap in Kilian (1999b) to obtain critical values.<sup>16</sup>

#### 4.2.2 Chao, Corradi and Swanson Tests

A limitation of the tests above is that they rule out possible dynamic misspecification under the null. A test which does not require correct dynamic specification and/or conditional homoskedasticity is proposed by Chao, Corradi, and Swanson (2001). Of note, however, is that the Clark and McCracken tests are one-sided while the Chao, Corradi and Swanson test are two-sided, and so may be less powerful in small samples. The test statistic is

$$m_P = P^{-1/2} \sum_{t=R}^{T-1} \hat{\epsilon}_{t+1} X_t, \quad (45)$$

where  $\hat{\epsilon}_{t+1} = y_{t+1} - \sum_{j=1}^{p-1} \hat{\beta}_{t,j} y_{t-j}$ ,  $X_t = (x_t, x_{t-1}, \dots, x_{t-k-1})'$ . We shall formulate the null and the alternative as

$$\begin{aligned} \tilde{H}_0 & : E(\epsilon_{t+1} x_{t-j}) = 0, j = 0, 1, \dots, k-1 \\ \tilde{H}_A & : E(\epsilon_{t+1} x_{t-j}) \neq 0 \text{ for some } j, j = 0, 1, \dots, k-1. \end{aligned}$$

---

<sup>15</sup>The tests are applied to the problem of comparing linear economic models of exchange rates in McCracken and Sapp (2004).

<sup>16</sup>For the case of  $h = 1$ , the limit distribution of  $ENC - T'$  corresponds with that of  $ENC - T$ , given in Proposition 4.2, and the limiting distribution is derived by McCracken (2000).

The idea underlying the test is very simple, if  $\alpha_1 = \alpha_2 = \dots = \alpha_k = 0$ , then  $\epsilon_t$  is uncorrelated with the past of  $X$ . Thus, models including lags of  $X_t$  do not “outperform” the smaller model. In the sequel we shall require the following assumption.

**CCS:**  $(y_t, x_t)$  are strictly stationary, strong mixing processes, with size  $\frac{-4(4+\delta)}{\delta}$ , for some  $\delta > 0$ , and  $E(y_t)^8 < \infty, E(x_t)^8 < \infty, E(\epsilon_t y_{t-j}) = 0, j = 1, 2, \dots, q$ .<sup>17</sup>

**Proposition 4.3 (from Theorem 1 in Chao, Corradi and Swanson (2001)):** Let CCS hold. As  $T \rightarrow \infty, P, R \rightarrow \infty, P/R \rightarrow \pi, 0 \leq \pi < \infty$ ,

(i) Under  $\tilde{H}_0$ , for  $0 < \pi < \infty$ ,

$$m_P \xrightarrow{d} N\left(0, S_{11} + 2(1 - \pi^{-1} \ln(1 + \pi))F' M S_{22} M F - (1 - \pi^{-1} \ln(1 + \pi))(F' M S_{12} + S'_{12} M F)\right)$$

In addition, for  $\pi = 0, m_P \xrightarrow{d} N(0, S_{11})$ , where  $F = E(Y_t X'_t), M = \text{plim} \left( \frac{1}{t} \sum_{j=q}^t Y_j Y'_j \right)^{-1}$ , and  $Y_j = (y_{j-1}, \dots, y_{j-q})'$ , so that  $M$  is a  $q \times q$  matrix,  $F$  is a  $q \times k$  matrix,  $Y_j$  is a  $k \times 1$  vector,  $S_{11}$  is a  $k \times k$  matrix,  $S_{12}$  is a  $q \times k$  matrix, and  $S_{22}$  is a  $q \times q$  matrix, with

$$S_{11} = \sum_{j=-\infty}^{\infty} E((X_t \epsilon_{t+1} - \mu)(X_{t-j} \epsilon_{t+1-j} - \mu)'),$$

where  $\mu = E(X_t \epsilon_{t+1}), S_{22} = \sum_{j=-\infty}^{\infty} E((Y_{t-1} \epsilon_t)(Y_{t-1-j} \epsilon_{t-j}'))$  and

$$S'_{12} = \sum_{j=-\infty}^{\infty} E((\epsilon_{t+1} X_t - \mu)(Y_{t-1-j} \epsilon_{t-j}')).$$

(ii) Under  $\tilde{H}_A$ ,  $\lim_{P \rightarrow \infty} \Pr\left(|\frac{m_p}{P^{1/2}}| > 0\right) = 1$ .

**Corollary 4.4 (from Corollary 2 in Chao, Corradi and Swanson (2001)):** Let Assumption CCS hold. As  $T \rightarrow \infty, P, R \rightarrow \infty, P/R \rightarrow \pi, 0 \leq \pi < \infty, l_T \rightarrow \infty, l_T/T^{1/4} \rightarrow 0$ ,

(i) Under  $\tilde{H}_0$ , for  $0 < \pi < \infty$ ,

$$\begin{aligned} m'_p &\left( \widehat{S}_{11} + 2(1 - \pi^{-1} \ln(1 + \pi))\widehat{F}' \widehat{M} \widehat{S}_{22} \widehat{M} \widehat{F} - (1 - \pi^{-1} \ln(1 + \pi))(\widehat{F}' \widehat{M} \widehat{S}_{12} + \widehat{S}'_{12} \widehat{M} \widehat{F})^{-1} \right) m_P \\ &\xrightarrow{d} \chi_k^2 \end{aligned} \tag{46}$$

---

<sup>17</sup>Note that the requirement  $E(\epsilon_t y_{t-j}) = 0, j = 1, 2, \dots, p$  is equivalent to the requirement that  $E(y_t | y_{t-1}, \dots, y_{t-p}) = \sum_{j=1}^{p-1} \beta_j y_{t-j}$ . However, we allow to dynamic misspecification under the null.

where  $\widehat{F} = \frac{1}{P} \sum_{t=R}^T Y_t X'_t$ ,  $\widehat{M} = \left( \frac{1}{P} \sum_{t=R}^{T-1} Y_t Y'_t \right)^{-1}$ , and  $\widehat{S}_{11} =$

$$\begin{aligned} & \frac{1}{P} \sum_{t=R}^{T-1} (\widehat{\epsilon}_{t+1} X_t - \widehat{\mu}_1) (\widehat{\epsilon}_{t+1} X_t - \widehat{\mu}_1)' \\ & + \frac{1}{P} \sum_{t=\tau}^{l_T} w_\tau \sum_{t=R+\tau}^{T-1} (\widehat{\epsilon}_{t+1} X_t - \widehat{\mu}_1) (\widehat{\epsilon}_{t+1-\tau} X_{t-\tau} - \widehat{\mu}_1)' \\ & + \frac{1}{P} \sum_{t=\tau}^{l_T} w_\tau \sum_{t=R+\tau}^{T-1} (\widehat{\epsilon}_{t+1-\tau} X_{t-\tau} - \widehat{\mu}_1) (\widehat{\epsilon}_{t+1} X_t - \widehat{\mu}_1)', \end{aligned}$$

where  $\widehat{\mu}_1 = \frac{1}{P} \sum_{t=R}^{T-1} \widehat{\epsilon}_{t+1} X_t$ ,

$$\begin{aligned} \widehat{S}'_{12} &= \frac{1}{P} \sum_{\tau=0}^{l_T} w_\tau \sum_{t=R+\tau}^{T-1} (\widehat{\epsilon}_{t+1-\tau} X_{t-\tau} - \widehat{\mu}_1) (Y_{t-1} \widehat{\epsilon}_t)' \\ &+ \frac{1}{P} \sum_{\tau=1}^{l_T} w_\tau \sum_{t=R+\tau}^{T-1} (\widehat{\epsilon}_{t+1} X_t - \widehat{\mu}_1) (Y_{t-1-\tau} \widehat{\epsilon}_{t-\tau})', \end{aligned}$$

and

$$\begin{aligned} \widehat{S}_{22} &= \frac{1}{P} \sum_{t=R}^{T-1} (Y_{t-1} \widehat{\epsilon}_t) (Y_{t-1} \widehat{\epsilon}_t)' + \\ & \frac{1}{P} \sum_{\tau=1}^{l_T} w_\tau \sum_{t=R+\tau}^{T-1} (Y_{t-1} \widehat{\epsilon}_t) (Y_{t-1-\tau} \widehat{\epsilon}_{t-\tau})' \\ &+ \frac{1}{P} \sum_{\tau=1}^{l_T} w_\tau \sum_{t=R+\tau}^{T-1} (Y_{t-1-\tau} \widehat{\epsilon}_{t-\tau}) (Y_{t-1} \widehat{\epsilon}_t)', \end{aligned}$$

with  $w_\tau = 1 - \frac{\tau}{l_T + 1}$ .

In addition, for  $\pi = 0$ ,  $m_p' \widehat{S}_{11} m_p \xrightarrow{d} \chi_k^2$ .

(ii) Under  $\tilde{H}_A$ ,  $m_p' \widehat{S}_{11}^{-1} m_p$  diverges at rate  $P$ .

Two final remarks: (i) note that the test can be easily applied to the case of multistep-ahead prediction, it just suffices to replace "1" with " $h$ " above. (ii) linearity of neither the null or the larger model is not required.

In fact the test, can be equally applied using residuals from a nonlinear model and using a nonlinear function of  $X_t$  as a test function.

### 4.3 Comparison of Multiple Models: The Reality Check

In the previous subsection, we considered the issue of choosing between two competing models. However, in a lot of situations many different competing models are available and we want to be able to choose the

best model from amongst them. When we estimate and compare a very large number of models using the same data set, the problem of data mining or data snooping is prevalent. Broadly speaking, the problem of data snooping is that a model may appear to be superior by chance and not because of its intrinsic merit (recall also the problem of sequential test bias). In other words, if we keep testing the null hypothesis of efficient markets, using the same data set, eventually we shall find a model that results in rejection. The data snooping problem is particularly serious when there is economic theory supporting an alternative hypothesis. For example, the data snooping problem in the context of evaluating trading rules has been pointed out by Brock, Lakonishok and LeBaron (1992), as well as Sullivan, Timmerman and White (1999,2001).

#### 4.3.1 White's Reality Check and Extensions

White (2000) proposes a novel approach for dealing with the issue of choosing amongst many different models. Suppose there are  $m$  models, and we select model 1 as our benchmark (or reference) model. Models  $i = 2, \dots, m$  are called the competitor (alternative) models. Typically, the benchmark model is either a simple model, our favorite model, or the most commonly used model. Given the benchmark model, the objective is to answer the following question: “Is there any model, amongst the set of  $m - 1$  competitor models, that yields more accurate predictions (for the variable of interest) than the benchmark?”.

In this section, let the generic forecast error be  $u_{i,t+1} = y_{t+1} - \kappa_i(Z^t, \theta_i^\dagger)$ , and let  $\hat{u}_{i,t+1} = y_{t+1} - \kappa_i(Z^t, \hat{\theta}_{i,t})$ , where  $\kappa_i(Z^t, \hat{\theta}_{i,t})$  is the conditional mean function under model  $i$ , and  $\hat{\theta}_{i,t}$  is defined as in Section 3.1. Assume that the set of regressors may vary across different models, so that  $Z^t$  is meant to denote the collection of all potential regressors. Following White (2000), define the statistic

$$S_P = \max_{k=2,\dots,m} S_P(1,k),$$

where

$$S_P(1,k) = \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (g(\hat{u}_{1,t+1}) - g(\hat{u}_{k,t+1})) , \quad k = 2, \dots, m,$$

The hypotheses are formulated as

$$H_0 : \max_{k=2,\dots,m} E(g(u_{1,t+1}) - g(u_{k,t+1})) \leq 0$$

$$H_A : \max_{k=2,\dots,m} E(g(u_{1,t+1}) - g(u_{k,t+1})) > 0,$$

where  $u_{k,t+1} = y_{t+1} - \kappa_k(Z^t, \theta_{k,t}^\dagger)$ , and  $\theta_{k,t}^\dagger$  denotes the probability limit of  $\theta_{i,t}$ .

Thus, under the null hypothesis, no competitor model, amongst the set of the  $m - 1$  alternatives, can provide a more (loss function specific) accurate prediction than the benchmark model. On the other hand,

under the alternative, at least one competitor (and in particular, the best competitor) provides more accurate predictions than the benchmark. Now, let **W1** and **W2** be as given in Section 3.1, and also assume the following.

**WH:** (i)  $\kappa_i$  is twice continuously differentiable on the interior of  $\Theta_i$  and the elements of  $\nabla_{\theta_i} \kappa_i(Z^t, \theta_i)$  and  $\nabla_{\theta_i}^2 \kappa_i(Z^t, \theta_i)$  are  $p$ -dominated on  $\Theta_i$ , for  $i = 2, \dots, n$ , with  $p > 2(2 + \psi)$ , where  $\psi$  is the same positive constant defined in **W1**; (ii)  $g$  is positive valued, twice continuously differentiable on  $\Theta_i$ , and  $g, g'$  and  $g''$  are  $p$ -dominated on  $\Theta_i$  with  $p$  defined as in (i); and (iii) let  $c_{kk} = \lim_{T \rightarrow \infty} \text{Var} \left( \frac{1}{\sqrt{T}} \sum_{t=s}^T (g(u_{1,t+1}) - g(u_{k,t+1})) \right)$ ,  $k = 2, \dots, n$ , define analogous covariance terms,  $c_{j,k}$ ,  $j, k = 2, \dots, n$ , and assume that  $[c_{j,k}]$  is positive semi-definite.

It is important to stress that for this test, at least one of the competitor models has to be nonnested with the benchmark model.<sup>18</sup> This is ensured by Assumption **WH**.

**Proposition 4.5: (Parts (i) and (iii) are from Proposition 2.2 in White (2000)):** Let **W1-W2** and **WH** hold. Then, under  $H_0$ ,

$$\max_{k=2,\dots,n} \left( S_P(1, k) - \sqrt{P} E(g(u_{1,t+1}) - g(u_{k,t+1})) \right) \xrightarrow{d} \max_{k=2,\dots,n} S(1, k), \quad (47)$$

where  $S = (S(1, 2), \dots, S(1, n))$  is a zero mean Gaussian process with covariance kernel given by  $V$ , with  $V$  a  $n \times n$  matrix, and

(i) If parameter estimation error vanishes (i.e. if either  $P/R$  does not go to zero and/or the same loss function is used for estimation and model evaluation,  $g = q$ , where  $q$  is again the objective function), then for  $i = 1, \dots, m-1$ ,  $V = [v_{i,i}] = S_{g_i g_i}$ , and

(ii) If parameter estimation error does not vanish (i.e. if  $P/R \rightarrow 0$  and  $g \neq q$ ), then for  $i, j = 1, \dots, m-1$

$$V = [v_{i,i}] = S_{g_i g_i} + 2\Pi \mu'_1 B_1^\dagger C_{11} B_1^\dagger \mu_1 + 2\Pi \mu'_i B_i^\dagger C_{ii} B_i^\dagger \mu_i - 4\Pi \mu'_1 B_1^\dagger C_{1i} B_i^\dagger \mu_i + 2\Pi S_{g_{iq_1}} B_1^\dagger \mu_1 - 2\Pi S_{g_{iq_i}} B_i^\dagger \mu_i,$$

$$\text{where } S_{g_i g_i} = \sum_{\tau=-\infty}^{\infty} E((g(u_{1,1}) - g(u_{i,1})) (g(u_{1,1+\tau}) - g(u_{i,1+\tau}))),$$

$$C_{ii} = \sum_{\tau=-\infty}^{\infty} E \left( \left( \nabla_{\theta_i} q_i(y_{1+s}, Z^s, \theta_i^\dagger) \right) \left( \nabla_{\theta_i} q_i(y_{1+s+\tau}, Z^{s+\tau}, \theta_i^\dagger) \right)' \right),$$

$$S_{g_{iq_i}} = \sum_{\tau=-\infty}^{\infty} E \left( (g(u_{1,1}) - g(u_{i,1})) \left( \nabla_{\theta_i} q_i(y_{1+s+\tau}, Z^{s+\tau}, \theta_i^\dagger) \right)' \right),$$

$$B_i^\dagger = \left( E \left( -\nabla_{\theta_i}^2 q_i(y_t, Z^{t-1}, \theta_i^\dagger) \right) \right)^{-1}, \mu_i = E(\nabla_{\theta_i} g(u_{i,t+1})), \text{ and } \Pi = 1 - \pi^{-1} \ln(1 + \pi).$$

$$(iii) \text{ Under } H_A, \Pr \left( \frac{1}{\sqrt{P}} |S_P| > \varepsilon \right) \rightarrow 1, \text{ as } P \rightarrow \infty.$$

**Proof:** For the proof of part (ii), see the Appendix.

Note that under the null, the least favorable case arises when  $E(g(u_{1,t+1}) - g(u_{k,t+1})) = 0, \forall k$ . In this case, the distribution of  $S_P$  coincides with that of  $\max_{k=2,\dots,n} (S_P(1, k) - \sqrt{P} E(g(u_{1,t+1}) - g(u_{k,t+1})))$ , so

---

<sup>18</sup>This is for the same reasons as discussed in the context of the Diebold and Mariano test.

that  $S_P$  has the above limiting distribution, which is a functional of a Gaussian process with a covariance kernel that reflects uncertainty due to dynamic misspecification and possibly to parameter estimation error. Additionally, when all competitor models are worse than the benchmark, the statistic diverges to minus infinity at rate  $\sqrt{P}$ . Finally, when only some competitor models are worse than the benchmark, the limiting distribution provides a conservative test, as  $S_P$  will always be smaller than  $\max_{k=2,\dots,n} \left( S_P(1,k) - \sqrt{P} E(g(u_{1,t+1}) - g(u_{k,t+1})) \right)$ , asymptotically. Of course, when  $H_A$  holds, the statistic diverges to plus infinity at rate  $\sqrt{P}$ .

We now outline how to obtain valid asymptotic critical values for the limiting distribution on the RHS of (47), regardless whether the contribution of parameter estimation error vanishes or not. As noted above, such critical values are conservative, except for the least favorable case under the null. We later outline two ways of alleviating this problem, one suggested by Hansen (2004a) and another, based on subsampling, suggested by Linton, Maasoumi and Whang (2004).

Recall that the maximum of a Gaussian process is not Gaussian in general, so that standard critical values cannot be used to conduct inference on  $S_P$ . As pointed out by White (2000), one possibility in this case is to first estimate the covariance structure and then draw 1 realization from an  $(n - 1)$ -dimensional normal with covariance equal to the estimated covariance structure. From this realization, pick the maximum value over  $k = 2, \dots, n$ . Repeat this a large number of times, form an empirical distribution using the maximum values over  $k = 2, \dots, n$ , and obtain critical values in the usual way. A drawback to this approach is that we need to rely on an estimator of the covariance structure based on the available sample of observations, which in many cases may be small relative to the number of models being compared. Furthermore, whenever the forecasting errors are not martingale difference sequences (as in our context), heteroskedasticity and autocorrelation consistent covariance matrices should be estimated, and thus a lag truncation parameter must be chosen. Another approach which avoids these problems involves using the stationary bootstrap of Politis and Romano (1994). This is the approach used by White (2000). In general, bootstrap procedures have been shown to perform well in a variety of finite sample contexts (see e.g. Diebold and Chen (1996)). White's suggested bootstrap procedure is valid for the case in which parameter estimation error vanishes asymptotically. His bootstrap statistic is given by:

$$S_P^{**} = \max_{k=2,\dots,m} |S_P^{**}(1,k)|, \quad (48)$$

where

$$S_P^{**}(1,k) = \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} ((g(\hat{u}_{1,t+1}^{**}) - g(\hat{u}_{1,t+1})) - (g(\hat{u}_{k,t+1}^{**}) - g(\hat{u}_{k,t+1}))),$$

and  $\hat{u}_{k,t+1}^{**} = y_{t+1}^{**} - \kappa_k(Z^{**}, \hat{\theta}_{k,t})$ , where  $y_{t+1}^{**}$   $Z^{**}$  denoted the resampled series. White uses the stationary

bootstrap by Politis and Romano (1994), but both the block bootstrap and stationary bootstrap deliver the same asymptotic critical values. Our approach to handling PEE is to apply the recursive PEE bootstrap outlined in Section 3.3 in order to obtain critical values which are asymptotically valid in the presence of non vanishing PEE.

Hereafter, let  $u_{i,t+1}^* = y_{t+1}^* - \kappa_i(Z^{*,t}, \theta_i^\dagger)$  and  $\hat{u}_{i,t+1}^* = y_{t+1}^* - \kappa_i(Z^{*,t}, \hat{\theta}_{i,t}^*)$ , where

$$\hat{\theta}_{i,t}^* = \arg \min_{\theta_i \in \Theta_i} \frac{1}{t} \sum_{j=s}^t q_i(y_j^*, Z^{*,j-1}, \theta_i), \quad R \leq t \leq T, \quad i = 1, \dots, m. \quad (49)$$

Also, let  $\tilde{u}_{i,t+1} = y_{t+1} - \kappa_i(Z^{*,t}, \hat{\theta}_{i,T})$ . Recall that  $y_t^*, Z^{*,t}$  is obtained via the resampling procedure described in Section 3.3. Define

$$S_P^* = \max_{k=2, \dots, m} S_P^*(1, k),$$

where

$$\begin{aligned} S_P^*(1, k) &= \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} ((g(\hat{u}_{1,t+1}^*) - g(\hat{u}_{1,t+1})) - (g(\hat{u}_{k,t+1}^*) - g(\hat{u}_{k,t+1}))) \\ &\quad + \frac{1}{T} \sum_{t=s}^T \nabla_{\theta_1} g(\hat{u}_{1,t+1}) \left( -\frac{1}{T} \sum_{t=s}^T \nabla_{\theta_1}^2 q_1(y_t, Z^{t-1}, \hat{\theta}_{1,T}) \right)^{-1} \\ &\quad \times \frac{1}{\sqrt{P}} \sum_{i=1}^{P-1} a_{R,i} \left( \nabla_{\theta_1} q_1(y_{R+i}, Z^{R+i-1}, \hat{\theta}_{1,T}) - \frac{1}{P} \sum_{i=1}^{P-1} \nabla_{\theta_1} q_1(y_{R+i}, Z^{R+i-1}, \hat{\theta}_{1,T}) \right) \\ &\quad - \frac{1}{T} \sum_{t=s}^T \nabla_{\theta_k} g(\hat{u}_{k,t+1}) \left( -\frac{1}{T} \sum_{t=s}^T \nabla_{\theta_k}^2 q_k(y_t, Z^{t-1}, \hat{\theta}_{k,T}) \right)^{-1} \\ &\quad \times \frac{1}{\sqrt{P}} \sum_{i=1}^{P-1} a_{R,i} \left( \nabla_{\theta_k} q_k(y_{R+i}, Z^{R+i-1}, \hat{\theta}_{k,T}) - \frac{1}{P} \sum_{i=1}^{P-1} \nabla_{\theta_k} q_k(y_{R+i}, Z^{R+i-1}, \hat{\theta}_{k,T}) \right), \quad (50) \end{aligned}$$

and where  $a_{R,i} = \frac{1}{R+i} + \frac{1}{R+i+1} + \dots + \frac{1}{R+P-1}$ ,  $\nabla_{\theta_1} g(\hat{u}_{1,t+1}) = g'(y_{t+1} - \kappa_1(Z^t, \hat{\theta}_{1,T})) \nabla_{\theta_1} \kappa_1(Z^t, \hat{\theta}_{1,T})$ .  $\nabla_{\theta_k} g(\tilde{u}_{k,t+1})$  is defined analogously, and with the notation  $g'$  and  $g''$  we mean the first and second derivatives of  $g$  with respect to its argument.

Note that there are two key differences between the statistics in (48) and (50). The first one is that in the definition of (48) we used an estimator constructed using the original sample rather than using resampled observations, as in (50). The second is that (48) does not include an adjustment term. Assuming that  $l_1$  and  $l_2$  are defined as in Section 3.3, the following results hold.

**Proposition 4.6 (Part (i) is from Corollary 2.6 in White (2000)):** Let **W1-W2** and **WH** hold.

(i) If  $P/R \rightarrow 0$  and/or  $g = q$ , then as  $P, R \rightarrow \infty$

$$P \left( \omega : \sup_{v \in \Re} \left| P_{R,P}^* \left( \max_{k=2, \dots, n} S_P^{**}(1, k) \leq v \right) - P \left( \max_{k=2, \dots, n} S_P^\mu(1, k) \leq v \right) \right| > \varepsilon \right) \rightarrow 0,$$

(ii) Assume that as  $P, R \rightarrow \infty$ ,  $l_1, l_2 \rightarrow \infty$ , and that  $\frac{l_2}{P^{1/4}} \rightarrow 0$  and  $\frac{l_1}{R^{1/4}} \rightarrow 0$ . Then, if  $P/R \rightarrow \pi > 0$  and  $g \neq q$ ,

$$P\left(\omega : \sup_{v \in \Re} \left| P_{R,P}^* \left( \max_{k=2,\dots,n} S_P^*(1,k) \leq v \right) - P \left( \max_{k=2,\dots,n} S_P^\mu(1,k) \leq v \right) \right| > \varepsilon\right) \rightarrow 0,$$

where

$$S_P^\mu(1,k) = S_P(1,k) - \sqrt{P}E(g(u_{1,t+1}) - g(u_{k,t+1})).$$

**Proof:** For the proof of part (ii), see the Appendix.

The above result suggests proceeding in the following manner. For any bootstrap replication, compute the bootstrap statistic,  $S_P^{**}$  or  $S_P^*$ . Perform  $B$  bootstrap replications ( $B$  large) and compute the quantiles of the empirical distribution of the  $B$  bootstrap statistics. Reject  $H_0$ , if  $S_P$  is greater than the  $(1 - \alpha)$ th-percentile of the relevant empirical bootstrap distribution. Otherwise, do not reject. Now, for all samples except a set with probability measure approaching zero,  $S_P$  has the same limiting distribution as the corresponding bootstrapped statistic when  $E(g(u_{1,t+1}) - g(u_{k,t+1})) = 0 \forall k$ , ensuring asymptotic size equal to  $\alpha$ . On the other hand, when one or more competitor models are strictly dominated by the benchmark, the rule provides a test with asymptotic size between 0 and  $\alpha$ . Under the alternative,  $S_P$  diverges to (plus) infinity, while the corresponding bootstrap statistic has a well defined limiting distribution, ensuring unit asymptotic power.

### 4.3.2 Hansen's Approach Applied to the Reality Check

As mentioned above, the critical values obtained via the empirical distribution of  $S_P^{**}$  or  $S_P^*$  are upper bounds whenever some competing models are strictly dominated by the benchmark. The issue of conservativeness is particularly relevant when a large number of dominated (bad) models are included in the analysis. In fact, such models do not contribute to the limiting distribution, but drive up the reality check  $p$ -values, which are obtained for the least favorable case under the null hypothesis. The idea of Hansen (2004a)<sup>19</sup> is to eliminate the models which are dominated, while paying careful attention to not eliminate relevant models.

In summary, Hansen defines the statistic

$$\tilde{S}_P = \max \left\{ \max_{k=2,\dots,m} \frac{S_P(1,k)}{\left( \widehat{\text{var}} \frac{1}{P} \sum_{t=R}^{T-1} (g(\hat{u}_{1,t+1}) - g(\hat{u}_{k,t+1})) \right)^{1/2}}, 0 \right\},$$

where  $\widehat{\text{var}} \frac{1}{P} \sum_{t=R}^{T-1} (g(\hat{u}_{1,t+1}) - g(\hat{u}_{k,t+1}))$  is defined in (51) below. In this way, the modified reality check statistic does not take into account strictly dominated models.

---

<sup>19</sup>A careful analysis of testing in the presence of composite null hypotheses is given in Hansen (2004b).

The idea of Hansen is also to impose the “entire” null (not only the least favorable component of the null) when constructing the bootstrap statistic. For this reason, he adds a recentering term. Define,

$$\hat{\mu}_k = \frac{1}{P} \sum_{t=R}^{T-1} (g(\hat{u}_{1,t+1}) - g(\hat{u}_{k,t+1})) \mathbf{1}\{g(\hat{u}_{1,t+1}) - g(\hat{u}_{k,t+1}) \geq A_{T,k}\},$$

where  $A_{T,k} = \frac{1}{4} T^{-1/4} \sqrt{\widehat{var} \frac{1}{P} \sum_{t=R}^{T-1} (g(\hat{u}_{1,t+1}) - g(\hat{u}_{k,t+1}))}$ ,

with

$$\begin{aligned} & \widehat{var} \frac{1}{P} \sum_{t=R}^{T-1} (g(\hat{u}_{1,t+1}) - g(\hat{u}_{k,t+1})) \\ &= B^{-1} \sum_{b=1}^B \left( \frac{1}{P} \sum_{t=R}^{T-1} ((g(\hat{u}_{1,t+1}) - g(\hat{u}_{k,t+1})) - (g(\hat{u}_{1,t+1}^*) - g(\hat{u}_{k,t+1}^*)))^2 \right), \end{aligned} \quad (51)$$

and where  $B$  denotes the number of bootstrap replications. Hansen’s bootstrap statistic is then defined as

$$\tilde{S}_P^* = \max_{k=2,\dots,m} \frac{\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} [ (g(\hat{u}_{1,t+1}^*) - g(\hat{u}_{k,t+1}^*)) - \hat{\mu}_k]}{\left( \widehat{var} \frac{1}{P} \sum_{t=R}^{T-1} (g(\hat{u}_{1,t+1}) - g(\hat{u}_{k,t+1})) \right)^{1/2}}$$

$P$ -values are then computed in terms of the number of times the statistic is smaller than the bootstrap statistic, and  $H_0$  is rejected if, say,  $\frac{1}{B} \sum_{b=1}^B \mathbf{1}\{\tilde{S}_P^* \leq \tilde{S}_P^*\}$  is below  $\alpha$ . This procedure is valid, provided that the effect of parameter estimation error vanishes.

#### 4.3.3 The Subsampling Approach Applied to the Reality Check

The idea of subsampling is based on constructing a sequence statistics using a (sub)sample of size  $b$ , where  $b$  grows with the sample size, but at a slower rate. Critical values are constructed using the empirical distribution of the sequence of statistics (see e.g. the book by Politis, Romano and Wolf (1999)). In the current context, let the subsampling size to be equal to  $b$ , where as  $P \rightarrow \infty$ ,  $b \rightarrow \infty$  and  $b/P \rightarrow 0$ . Define

$$S_{P,a,b} = \max_{k=2,\dots,n} S_{P,a,b}(1, k), \quad a = R, \dots, T - b - 1$$

where

$$S_{P,a,b}(1, k) = \frac{1}{\sqrt{b}} \sum_{t=a}^{a+b-1} (g(\hat{u}_{1,t+1}) - g(\hat{u}_{k,t+1})), \quad k = 2, \dots, m.$$

Compute the empirical distribution of  $S_{P,a,b}$  using  $T - b - 1$  statistics constructed using  $b$  observations. The rule is to reject if we get a value for  $S_P$  larger then the  $(1 - \alpha)$ -critical value of the (subsample) empirical distribution, and do not reject otherwise. If  $\max_{k=2,\dots,m} E(g(u_{1,t+1}) - f(g_{k,t+1})) = 0$ , then this rule gives a test with asymptotic size equal to  $\alpha$ , while if  $\max_{k=2,\dots,m} E(g(u_{1,t+1}) - f(g_{k,t+1})) < 0$  (i.e. if

all models are dominated by the benchmark), then the rule gives a test with asymptotic size equal to zero. Finally, under the alternative,  $S_{P,a,b}$  diverges at rate  $\sqrt{b}$ , ensuring unit asymptotic power, provided that  $b/P \rightarrow 0$ . The advantage of subsampling over the block bootstrap, is that the test then has correct size when  $\max_{k=2,\dots,m} E(g(u_{1,t+1}) - f(g_{k,t+1})) = 0$ , while the bootstrap approach gives conservative critical values, whenever  $E(g(u_{1,t+1}) - f(g_{k,t+1})) < 0$  for some  $k$ . Note that the subsampling approach is valid also in the case of non vanishing parameter estimation error. This is because each subsample statistic properly mimics the distribution of the actual statistic. On the other hand the subsampling approach has two drawbacks. First, subsampling critical values are based on a sample of size  $b$  instead than  $P$ . Second, the finite sample power may be rather low, as the subsampling quantiles under the alternative diverge at rate  $\sqrt{b}$ , while bootstrap quantiles are bounded under both hypotheses. In a recent paper, Linton, Maasoumi and Whang (2004) apply the subsampling approach to the problem of testing for stochastic dominance; a problem characterized by a composite null, as in the reality check case.

#### 4.3.4 The False Discovery Rate Approach Applied to the Reality Check

Another way to avoid sequential testing bias is to rely on bounds, such as (modified) Bonferroni bounds. However, a well known drawback of such an approach is that it is conservative, particularly when we compare a large number of models. Recently, a new approach, based on the false discovery rate (FDR) has been suggested by Benjamini and Hochberg (1995), for the case of independent statistics. their approach has been extended to the case of dependent statistics by Benjamini and Yekutieli (2001).<sup>20</sup> The FDR approach allows one to select among alternative groups of models, in the sense that one can assess which group(s) contribute to the rejection of the null. The FDR approach has the objective of controlling the expected number of false rejections, and in practice one computes p-values associated with  $m$  hypotheses, and orders these  $p$ -values in increasing fashion, say  $P_1 \leq \dots \leq P_i \leq \dots \leq P_m$ . Then, all hypotheses characterized by  $P_i \leq (1 - (i - 1)/m)\alpha$  are rejected, where  $\alpha$  is a given significance level. Such an approach, though less conservative than Hochberg's (1988) approach, is still conservative as it provides bounds on p-values. More recently, Storey (2003) introduces the  $q$ -value of a test statistic, which is defined as the minimum possible false discovery rate for the null is rejected. McCracken and Sapp (2004) implement the  $q$ -value approach for the comparison of multiple exchange rate models. Overall, we think that a sound practical strategy could be to first implement the above reality check type tests. These tests can then be complemented by using a

---

<sup>20</sup>Benjamini and Yekutieli (2001) show that the Benjamini and Hochberg (1995) FDR is valid when the statistics have positive regression dependency. This condition allows for multivariate test statistics with a non diagonal correlation matrix.

multiple comparison approach, yielding a better overall understanding concerning which model(s) contribute to the rejection of the null, if it is indeed rejected. If the null is not rejected, then one simply chooses the benchmark model. Nevertheless, even in this case, it may not hurt to see whether some of the individual hypotheses in their joint null hypothesis are rejected via a multiple test comparison approach.

#### 4.4 A Predictive Accuracy Test That is Consistent Against Generic Alternatives

So far we have considered tests for comparing one model against a fixed number of alternative models. Needless to say, such tests have power only against a given alternative. However, there may clearly be some other model with greater predictive accuracy. This is a feature of predictive ability tests which has already been addressed in the consistent specification testing literature (see e.g. Bierens (1982, 1990), Bierens and Ploberger (1997), de Jong (1996), Hansen (1996), Lee, Granger and White (1993), Stinchcombe and White (1998)).

Corradi and Swanson (2002) draw on both the consistent specification and predictive accuracy testing literatures, and propose a test for predictive accuracy which is consistent against generic nonlinear alternatives, and which is designed for comparing nested models. The test is based on an out-of-sample version of the integrated conditional moment (ICM) test of Bierens (1982,1990) and Bierens and Ploberger (1997).

Summarizing, assume that the objective is to test whether there exists any unknown alternative model that has better predictive accuracy than a given benchmark model, for a given loss function. A typical example is the case in which the benchmark model is a simple autoregressive model and we want to check whether a more accurate forecasting model can be constructed by including possibly unknown (non)linear functions of the past of the process or of the past of some other process(es).<sup>21</sup> Although this is the case that we focus on, the benchmark model can in general be any (non)linear model. One important feature of this test is that the same loss function is used for in-sample estimation and out-of-sample prediction (see Granger (1993) and Weiss (1996)).

Let the benchmark model be

$$y_t = \theta_{1,1}^\dagger + \theta_{1,2}^\dagger y_{t-1} + u_{1,t}, \quad (52)$$

where  $\theta_1^\dagger = (\theta_{1,1}^\dagger, \theta_{1,2}^\dagger)' = \arg \min_{\theta_1 \in \Theta_1} E(q(y_t - \theta_{1,1} - \theta_{1,2}y_{t-1}))$ ,  $\theta_1 = (\theta_{1,1}, \theta_{1,2})'$ ,  $y_t$  is a scalar,  $q = g$ , as the same loss function is used both for in-sample estimation and out-of-sample predictive evaluation, and

---

<sup>21</sup>For example, Swanson and White (1997) compare the predictive accuracy of various linear models against neural network models using both in-sample and out-of-sample model selection criteria.

everything else is defined above. The generic alternative model is:

$$y_t = \theta_{2,1}^\dagger(\gamma) + \theta_{2,2}^\dagger(\gamma)y_{t-1} + \theta_{2,3}^\dagger(\gamma)w(Z^{t-1}, \gamma) + u_{2,t}(\gamma), \quad (53)$$

where  $\theta_2^\dagger(\gamma) = (\theta_{2,1}^\dagger(\gamma), \theta_{2,2}^\dagger(\gamma), \theta_{2,3}^\dagger(\gamma))' = \arg \min_{\theta_2 \in \Theta_2} E(q(y_t - \theta_{2,1} - \theta_{2,2}y_{t-1} - \theta_{2,3}w(Z^{t-1}, \gamma)))$ ,  $\theta_2(\gamma) = (\theta_{2,1}(\gamma), \theta_{2,2}(\gamma), \theta_{2,3}(\gamma))'$ , and  $\theta_2 \in \Theta_2$ , where  $\Gamma$  is a compact subset of  $\Re^d$ , for some finite  $d$ . The alternative model is called “generic” because of the presence of  $w(Z^{t-1}, \gamma)$ , which is a generically comprehensive function, such as Bierens’ exponential, a logistic, or a cumulative distribution function (see e.g. Stinchcombe and White (1998) for a detailed explanation of generic comprehensiveness). One example has  $w(Z^{t-1}, \gamma) = \exp(\sum_{i=1}^s \gamma_i \Phi(X_{t-i}))$ , where  $\Phi$  is a measurable one to one mapping from  $\Re$  to a bounded subset of  $\Re$ , so that here  $Z^t = (X_t, \dots, X_{t-s+1})$ , and we are thus testing for nonlinear Granger causality. The hypotheses of interest are:

$$H_0 : E(g(u_{1,t+1}) - g(u_{2,t+1}(\gamma))) = 0 \quad (54)$$

$$H_A : E(g(u_{1,t+1}) - g(u_{2,t+1}(\gamma))) > 0. \quad (55)$$

Clearly, the reference model is nested within the alternative model, and given the definitions of  $\theta_1^\dagger$  and  $\theta_2^\dagger(\gamma)$ , the null model can never outperform the alternative. For this reason,  $H_0$  corresponds to equal predictive accuracy, while  $H_A$  corresponds to the case where the alternative model outperforms the reference model, as long as the errors above are loss function specific forecast errors. It follows that  $H_0$  and  $H_A$  can be restated as:

$$H_0 : \theta_{2,3}^\dagger(\gamma) = 0 \text{ versus } H_A : \theta_{2,3}^\dagger(\gamma) \neq 0,$$

for  $\forall \gamma \in \Gamma$ , except for a subset with zero Lebesgue measure. Now, given the definition of  $\theta_2^\dagger(\gamma)$ , note that

$$E \left( g'(y_{t+1} - \theta_{2,1}^\dagger(\gamma) - \theta_{2,2}^\dagger(\gamma)y_t - \theta_{2,3}^\dagger(\gamma)w(Z^t, \gamma)) \times \begin{pmatrix} -1 \\ -y_t \\ -w(Z^t, \gamma) \end{pmatrix} \right) = 0,$$

where  $g'$  is defined as above. Hence, under  $H_0$  we have that  $\theta_{2,3}^\dagger(\gamma) = 0$ ,  $\theta_{2,1}^\dagger(\gamma) = \theta_{1,1}^\dagger$ ,  $\theta_{2,2}^\dagger(\gamma) = \theta_{1,2}^\dagger$ , and  $E(g'(u_{1,t+1})w(Z^t, \gamma)) = 0$ . Thus, we can once again restate  $H_0$  and  $H_A$  as:

$$H_0 : E(g'(u_{1,t+1})w(Z^t, \gamma)) = 0 \text{ versus } H_A : E(g'(u_{1,t+1})w(Z^t, \gamma)) \neq 0, \quad (56)$$

for  $\forall \gamma \in \Gamma$ , except for a subset with zero Lebesgue measure. Finally, define  $\widehat{u}_{1,t+1} = y_{t+1} - \begin{pmatrix} 1 & y_t \end{pmatrix} \widehat{\theta}_{1,t}$ .

The test statistic is:

$$M_P = \int_{\Gamma} m_P(\gamma)^2 \phi(\gamma) d\gamma, \quad (57)$$

and

$$m_P(\gamma) = \frac{1}{P^{1/2}} \sum_{t=R}^{T-1} g'(\hat{u}_{1,t+1}) w(Z^t, \gamma), \quad (58)$$

where  $\int_{\Gamma} \phi(\gamma) d\gamma = 1$ ,  $\phi(\gamma) \geq 0$ , and  $\phi(\gamma)$  is absolutely continuous with respect to Lebesgue measure. In the sequel, we need:

**NV1:** (i)  $(x_t, z_t)$  is a strictly stationary and absolutely regular strong mixing sequence with size  $-4(4+\psi)/\psi$ ,  $\psi > 0$ , (ii)  $g$  is three times continuously differentiable in  $\beta$ , over the interior of  $B$ , and  $\nabla_{\beta}g$ ,  $\nabla_{\beta}^2g$ ,  $\nabla_{\beta}g'$ ,  $\nabla_{\beta}^2g'$  are  $2r$ -dominated uniformly in  $B$ , with  $r \geq 2(2 + \psi)$ , (iii)  $E(-\nabla_{\beta}^2g_t(\beta))$  is negative definite, uniformly in  $B$ , (iv)  $w$  is a bounded, twice continuously differentiable function on the interior of  $\Gamma$  and  $\nabla_{\gamma}w(z^t, \gamma)$  is bounded uniformly in  $\Gamma$  and (v)  $\nabla_{\gamma}\nabla_{\beta}g'_t(\beta)w(z^{t-1}, \gamma)$  is continuous on  $B \times \Gamma$ ,  $\Gamma$  a compact subset of  $R^d$  and is  $2r$ -dominated uniformly in  $B \times \Gamma$ , with  $r \geq 2(2 + \psi)$ .

**NV2:** (i)  $E(g'(x_t - \beta_1 - \beta_2 x_{t-1})) > E(g'(x_t - \beta_1^* - \beta_2^* x_{t-1}))$ ,  $\forall \beta \neq \beta^*$  and

(ii)  $E(g'(x_t - \delta_1 - \delta_2 x_{t-1} - \delta_3 w(z^{t-1}, \gamma))) > \inf_{\gamma} E(g'(x_t - \delta_1^*(\gamma) - \delta_2^*(\gamma)x_{t-1} - \delta_3^*(\gamma)w(z^{t-1}, \gamma)))$  for  $\delta \neq \delta^*(\gamma)$ .

**NV3:**  $T = R + P$ , and as  $T \rightarrow \infty$ ,  $\frac{P}{R} \rightarrow \pi$ , with,  $0 \leq \pi < \infty$ .

**NV4:** For any  $t, s; \forall i, j, k = 1, 2$ ; and for  $\Delta < \infty$ :

(i)  $E \left( \sup_{\beta \times \gamma \times \gamma^+ \in B \times \Gamma \times \Gamma} \left| g'_t(\beta) w(z^{t-1}, \gamma) \nabla_{\beta}^k g'_s(\beta) w(z^{s-1}, \gamma^+) \right|^4 \right) < \Delta$ ,

where  $\nabla_{\beta}^k(\cdot)$  denotes the  $k$ -th element of the derivative of its argument with respect to  $\beta$ .

(ii)  $E \left( \sup_{\beta \in B} \left| (\nabla_{\beta}^k (\nabla_{\beta}^i g_t(\beta)) \nabla_{\beta}^j g_s(\beta)) \right|^4 \right) < \Delta$ , and

(iii)  $E \left( \sup_{\beta \times \gamma \in B \times \Gamma} \left| (g'_t(\beta) w(z^{t-1}, \gamma) \nabla_{\beta}^k (\nabla_{\beta}^j g_s(\beta))) \right|^4 \right) < \Delta$ .

**Theorem 4.7 (from Theorem 1 in Corradi and Swanson (2002)):** Let NV1-NV3 hold. Then, the following results hold:

(i) Under  $H_0$ ,

$$M_P = \int_{\Gamma} m_P(\gamma)^2 \phi(\gamma) d\gamma \xrightarrow{d} \int_{\Gamma} Z(\gamma)^2 \phi(\gamma) d\gamma,$$

where  $m_P(\gamma)$  is defined in equation (58) and  $Z$  is a Gaussian process with covariance kernel given by:

$$\begin{aligned} K(\gamma_1, \gamma_2) &= S_{gg}(\gamma_1, \gamma_2) + 2\Pi F(\beta^*, \gamma_1)' B(\beta^*)^{-1} S_{hh} B(\beta^*)^{-1} F(\beta^*, \gamma_2) + \Pi F(\beta^*, \gamma_1)' B(\beta^*)^{-1} S_{gh}(\gamma_2) \\ &\quad + \Pi F(\beta^*, \gamma_2)' B(\beta^*)^{-1} S_{gh}(\gamma_1), \end{aligned}$$

with  $F(\beta^*, \gamma) = E(\nabla_{\beta}(g'_{t+1}(\beta^*)w(z^t, \gamma)))$ ,  $B(\beta^*)^{-1} = (-E(\nabla_{\beta}^2g(\beta^*)))^{-1}$ ,

$S_{gg}(\gamma_1, \gamma_2) = \sum_{j=-\infty}^{\infty} E(g'_q(\beta^*)w(z^{q-1}, \gamma_1)g'_{q+j}(\beta^*)w(z^{q+j-1}, \gamma_2))$ ,

$S_{hh} = \sum_{j=-\infty}^{\infty} E(\nabla_{\beta}g_1(\beta^*)\nabla_{\beta}g_{1+j}(\beta^*))'$ ,

$$S_{gh}(\gamma_1) = \sum_{j=-\infty}^{\infty} E(g'_q(\beta^*)w(z^{q-1}, \gamma_1)\nabla_{\beta}g_{q+j}(\beta^*)'),$$

$\Pi = 1 - \pi^{-1} \ln(1 + \pi)$ , for  $\pi > 0$  and  $\Pi = 0$  for  $\pi = 0$ ,  $z^q = (z_1, \dots, z_q)'$ , and  $\gamma, \gamma_1, \gamma_2$  are generic elements of  $\Gamma$ .

(ii) Under  $H_A$ , for  $\varepsilon > 0$  and  $\delta < 1$ ,

$$\lim_{P \rightarrow \infty} \Pr \left( \frac{1}{P^\delta} \int_{\Gamma} m_P(\gamma)^2 \phi(\gamma) d\gamma > \varepsilon \right) = 1.$$

Thus, the limiting distribution under  $H_0$  is a Gaussian process with a covariance kernel that reflects both the dependence structure of the data and, for  $\pi > 0$ , the effect of parameter estimation error. Hence, critical values are data dependent and cannot be tabulated.

Valid asymptotic critical values can be obtained via the conditional p-value approach, first suggested by Hansen (1996). Recently Inoue (2001) has extended this approach to allow for non-martingale difference score functions. However, Inoue's approach does not take into account non vanishing parameter estimation error. For the current purposes, it suffices to extend Inoue's result to the case of nonvanishing parameter estimation error.

Let  $\epsilon_t, \eta_t$  be i.i.d.  $N(0, 1/l)$  random variables, with  $E(\epsilon_t \eta_s) = 0, \forall t, s$  and where  $l$  plays the role of the blocksize in a block bootstrap, or equivalently of the lag truncation parameter in the estimation of the HAC covariance matrix. The appropriate "simulated" statistic is:

$$m_P^*(\gamma) = m_P^{*(1)}(\gamma) + m_P^{*(2)}(\gamma),$$

where

$$m_P^{*(1)}(\gamma) = \frac{1}{P^{1/2}} \sum_{t=R}^{T-l} \sum_{i=t}^{t+l-1} \left( g'(\hat{u}_{0,i+1}) w(z^i, \gamma) + \widehat{\Pi} \widehat{F}(\widehat{\beta}_T, \gamma)' \widehat{B}(\widehat{\beta}_T)^{-1} \nabla_{\beta} g_i(\widehat{\beta}_T) \right) \quad (59)$$

with  $\hat{u}_{0,i+1} = x_{i+1} - \tilde{x}_i \widehat{\beta}_i$  and

$$m_P^{*(2)}(\gamma) = (2\widehat{\Pi} - \widehat{\Pi}^2)^{1/2} \frac{1}{P^{1/2}} \sum_{t=R}^{T-l} \sum_{i=t}^{t+l-1} \widehat{F}(\widehat{\beta}_T, \gamma)' \widehat{B}(\widehat{\beta}_T)^{-1} \nabla_{\beta} g_i(\widehat{\beta}_T),$$

with  $\widehat{\Pi}$ ,  $\widehat{F}(\widehat{\beta}_T, \gamma)', \widehat{B}(\widehat{\beta}_T)^{-1}$  defined as above.<sup>22</sup>

In order to motivate the use of this statistic, it is first worth considering the case in which we set  $l = 1$  and  $\Pi = 0$ . In particular, consider the case where the block length is unity, and there is no parameter estimation error ( $\Pi = 0$ ). This is the same framework used in Hansen (1996), and in this case we can write  $m_P^*(\gamma) = m_P^{*(1)}(\gamma) = \frac{1}{P^{1/2}} \sum_{t=R}^{T-1} \epsilon_t (g'(\hat{u}_{0,i+1}) w(z^i, \gamma))$ , as  $m_P^{*(2)}(\gamma) = 0$ . Note that conditional on the

---

<sup>22</sup>Note that the results reported below also hold when  $\widehat{F}(\widehat{\beta}_T, \gamma)', \widehat{B}(\widehat{\beta}_T)^{-1}$  are replaced with  $\widehat{F}(\widehat{\beta}_t, \gamma)', \widehat{B}_t(\widehat{\beta}_t)^{-1}$ .

sample,  $m_P^*(\gamma)$  is a zero mean normal random variable, with variance equal to  $\frac{1}{P} \sum_{t=R}^{T-1} (g'(\hat{u}_{0,i+1})w(z^i, \gamma))^2$ , which converges almost surely to the second moment of  $f'(u_{0,i+1})g(z^i, \gamma)$ , which in turn only coincides with the long run variance of  $m_P(\gamma) = \frac{1}{P^{1/2}} \sum_{t=R}^{T-1} g'(\hat{u}_{0,t+1})w(z^t, \gamma)$  (i.e.  $K(\gamma, \gamma)$ ) when  $g'(u_{0,i+1})w(z^i, \gamma)$  is a martingale difference sequence and when there is no parameter estimation error. Now, consider a generic value for  $l$ . That is, consider  $m_P^*(\gamma) = m_P^{*(1)}(\gamma) = \frac{1}{P^{1/2}} \sum_{t=R}^{T-l} \epsilon_t \sum_{i=t}^{t+l-1} (g'(\hat{u}_{0,i+1})w(z^i, \gamma))$ . In this case, conditional on the sample,  $m_P^*(\gamma)$  is a zero mean normal random variable, with variance equal to  $\frac{1}{Pl} \sum_{t=R}^{T-l} \left( \sum_{i=t}^{t+l-1} g'(\hat{u}_{0,i+1})w(z^i, \gamma) \right)^2$ , which converges almost surely to  $S_{gg}(\gamma, \gamma)$ , as defined above. However,  $S_{gg}(\gamma, \gamma)$  only coincides with  $K(\gamma, \gamma)$  when there is no parameter estimation error. This, in turn, suggests accounting for parameter estimation error by writing

$$m_P^*(\gamma) = m_P^{*(1)}(\gamma) = \frac{1}{P^{1/2}} \sum_{t=R}^{T-l} \epsilon_t \sum_{i=t}^{t+l-1} \left( g'(\hat{u}_{0,i+1})w(z^i, \gamma) + \widehat{\Pi} \widehat{F}(\widehat{\beta}_T, \gamma)' \widehat{B}(\widehat{\beta}_T)^{-1} \nabla_\beta g_i(\widehat{\beta}_T) \right).$$

Here, we capture data dependence and parameter estimation error. However, the variance of the simulated statistic in this case converges to some positive definite kernel which differs from  $K(\gamma, \gamma)$  by one constant term. In particular, the second term in the definition of  $K(\gamma, \gamma)$  is multiplied by  $\Pi^2$  instead of  $2\Pi$ . This explains why we need to define  $m_P^{*(2)}(\gamma)$ , which serves the desired role, given that  $\epsilon_t$  and  $\eta_t$  are uncorrelated.

To recap how one accounts for parameter estimation error in the simulated statistic, notice that conditionally on the sample, and for all samples except a set of measure zero,

$$\frac{1}{P^{1/2}} \sum_{t=R}^{T-l} \epsilon_t \sum_{i=t}^{t+l-1} g'(\hat{u}_{0,i+1})w(z^i, \gamma) \sim N \left( 0, \frac{1}{Pl} \sum_{t=R}^{T-l} \left( \sum_{i=t}^{t+l-1} g'(\hat{u}_{0,i+1})w(z^i, \gamma) \right)^2 \right)$$

and

$$\frac{1}{P^{1/2}} \sum_{t=R}^{T-l} \epsilon_t \sum_{i=t}^{t+l-1} g'(u_{0,i+1})w(z^i, \gamma) \sim N \left( 0, \frac{1}{Pl} \sum_{t=R}^{T-l} \left( \sum_{i=t}^{t+l-1} g'(u_{0,i+1})w(z^i, \gamma) \right)^2 \right).$$

Under the assumptions given above, and as  $P \rightarrow \infty$ , these two variance expressions converge to the same limit, for all samples except a set of measure zero. Thus, the effect of parameter estimation error in the simulated statistic would vanish if the second term were not added to  $m_P^{*(1)}(\gamma)$ . However, the second term in (59) only provides a consistent estimator of the contribution of parameter estimation error up to a constant depending on  $\Pi$ . To overcome this additional problem one can add  $m_P^{*(2)}(\gamma)$  to  $m_P^*(\gamma)$ , where  $m_P^{*(2)}(\gamma)$  is normally distributed, and is independent of  $m_P^{*(1)}(\gamma)$ , conditional on the sample and for all samples except a set of measure zero. This result is summarized in the following theorem.

**Theorem 4.8 (from Theorem 2 in Corradi and Swanson (2002)):** Let **NV1-NV4** hold. Also, assume that as  $P \rightarrow \infty$ ,  $l \rightarrow \infty$  and  $\frac{l(\log P)^{1/2}}{P^{1/4}} \rightarrow 0$ . Then, conditional on the sample and for all samples except a set of measure zero, the following results hold:

(i) Under  $H_0$ ,

$$M_P^* = \int_{\Gamma} m_P^*(\gamma)^2 \phi(\gamma) d\gamma \xrightarrow{d^*} \int_{\Gamma} Z(\gamma)^2 \phi(\gamma) d\gamma, \text{ a.s. } -\omega,$$

where  $d^*$  denotes convergence in distribution with respect to  $P^*$ ,  $P^*$  is the probability law governing  $\epsilon_t$  and  $\eta_t$ , conditional on the sample,  $Z$  is a Gaussian process with the same covariance as that given in Theorem 1, and  $a.s. - \omega$  means conditional on the sample, and for all samples except a set of measure zero.

(ii) Under  $H_A$ ,  $M_P^* = O_{P^*}(l)$ ,  $a.s. - \omega$ .

Thus,  $M_P$  and  $M_P^*$  have the same limiting distribution, conditional on the sample and for all samples except a set of measure zero, under  $H_0$ . Under  $H_A$ ,  $M_P$  diverges to infinity at rate  $P$  while  $M_P^*$  diverges at most at rate  $l$ , conditionally on the sample and for all samples except a set of measure zero. For any independent draw of  $\epsilon_t, \eta_t$ ,  $t = R, \dots, T-1$ , it thus suffices to compute  $M_P^*$ . By carrying out a large number of draws of  $\epsilon_t, \eta_t$ , percentiles of this simulated statistic can be obtained. The decision rule in this case is to reject (do not reject)  $H_0$  if the value of  $M_P$  which is obtained is above (equal to or below) the  $(1-\alpha)th$ -percentile. This rule provides a test with asymptotic size equal to  $\alpha$ , and unit asymptotic power.

Alternative, valid critical values can be obtained by applying the block bootstrap for parameter estimation error in recursive or rolling estimation schemes, outlined in Section 3.3.

## 5 Comparison of (Multiple) Misspecified Predictive Density Models

In Section 2 we outlined several tests for the null hypothesis of correct specification of the conditional distribution (some of which allowed for dynamic misspecification). Nevertheless, and as discussed above, most models are approximations of reality and therefore they are typically misspecified, and not just dynamically! In Section 4, we have seen that much of the recent literature on evaluation of point forecast models has already acknowledged the fact that models are typically misspecified. The purpose of this section is to merge these two strands of the literature and discuss recent tests for comparing misspecified conditional distribution models.

### 5.1 The Kullback-Leibler Information Criterion Approach

A well known measure of distributional accuracy is the Kullback-Leibler Information Criterion (KLIC), according to which we choose the model which minimizes the KLIC (see e.g. White (1982), Vuong (1989),

Giacomini (2002), and Kitamura (2002)). In particular, choose model 1 over model 2, if

$$E(\log f_1(Y_t|Z^t, \theta_1^\dagger) - \log f_2(Y_t|Z^t, \theta_2^\dagger)) > 0.$$

For the *iid* case, Vuong (1989) suggests a likelihood ratio test for choosing the conditional density model that is closer to the “true” conditional density in terms of the KLIC. Giacomini (2002) suggests a weighted version of the Vuong likelihood ratio test for the case of dependent observations, while Kitamura (2002) employs a KLIC based approach to select among misspecified conditional models that satisfy given moment conditions.<sup>23</sup> Furthermore, the KLIC approach has recently been employed for the evaluation of dynamic stochastic general equilibrium models (see e.g. Schorfheide (2000), Fernandez-Villaverde and Rubio-Ramirez (2004), and Chan, Gomes and Schorfheide (2002)). For example, Fernandez-Villaverde and Rubio-Ramirez (2004) show that the KLIC-best model is also the model with the highest posterior probability.

The KLIC is a sensible measure of accuracy, as it chooses the model which on average gives higher probability to events which have actually occurred. Also, it leads to simple likelihood ratio type tests which have a standard limiting distribution and are not affected by problems associated with accounting for PEE.

However, it should be noted that if one is interested in measuring accuracy over a specific region, or in measuring accuracy for a given conditional confidence interval, say, this cannot be done in as straightforward manner using the KLIC. For example, if we want to evaluate the accuracy of different models for approximating the probability that the rate of inflation tomorrow, given the rate of inflation today, will be between 0.5% and 1.5%, say, using the KLIC.

## 5.2 A Predictive Density Accuracy Test for Comparing Multiple Misspecified Models

Corradi and Swanson (2003c,d) introduce a measure of distributional accuracy, which can be interpreted as a distributional generalization of mean square error. In addition, Corradi and Swanson (2003c) apply this measure to the problem of selecting amongst multiple misspecified predictive density models. In this section we discuss these contributions to the literature.

### 5.2.1 A Mean Square Error Measure of Distributional Accuracy

As usual, consider forming parametric conditional distributions for a scalar random variable,  $y_t$ , given  $Z^t$ , where  $Z^t = (y_{t-1}, \dots, y_{t-s_1}, X_t, \dots, X_{t-s_2+1})$  with  $s_1, s_2$  finite. Define the group of conditional distribution

---

<sup>23</sup>Of note is that White (1982) shows that quasi maximum likelihood estimators minimize the KLIC, under mild conditions.

models from which one is to select a “best” model as  $F_1(u|Z^t, \theta_1^\dagger), \dots, F_m(u|Z^t, \theta_m^\dagger)$ , and define the true conditional distribution as

$$F_0(u|Z^t, \theta_0) = \Pr(y_t \leq u|Z^t).$$

Hereafter, assume that  $\theta_i^\dagger \in \Theta_i$ , where  $\Theta_i$  is a compact set in a finite dimensional Euclidean space, and let  $\theta_i^\dagger$  be the probability limit of a quasi maximum likelihood estimator (QMLE) of the parameters of the conditional distribution under model  $i$ . If model  $i$  is correctly specified, then  $\theta_i^\dagger = \theta_0$ . If  $m > 2$ , follow White (2000). Namely, choose a particular conditional distribution model as the “benchmark” and test the null hypothesis that no competing model can provide a more accurate approximation of the “true” conditional distribution, against the alternative that at least one competitor outperforms the benchmark model. Needless to say, pairwise comparison of alternative models, in which no benchmark need be specified, follows as a special case. In this context, measure accuracy using the above distributional analog of mean square error. More precisely, define the mean square (approximation) error associated with model  $i$ ,  $i = 1, \dots, m$ , in terms of the average over  $U$  of  $E \left( \left( F_i(u|Z^t, \theta_i^\dagger) - F_0(u|Z^t, \theta_0) \right)^2 \right)$ , where  $u \in U$ , and  $U$  is a possibly unbounded set on the real line, and the expectation is taken with respect to the conditioning variables. In particular, model 1 is more accurate than model 2, if

$$\int_U E \left( \left( F_1(u|Z^t, \theta_1^\dagger) - F_0(u|Z^t, \theta_0) \right)^2 - \left( F_2(u|Z^t, \theta_2^\dagger) - F_0(u|Z^t, \theta_0) \right)^2 \right) \phi(u) du < 0,$$

where  $\int_U \phi(u) du = 1$  and  $\phi(u) \geq 0$ , for all  $u \in U \subset \mathbb{R}$ . This measure essentially integrates over different quantiles of the conditional distribution. For any given evaluation point, this measure defines a norm and it implies a standard goodness of fit measure. Note, that this measure of accuracy leads to straightforward evaluation of distributional accuracy over a given region of interest, as well as to straightforward evaluation of specific quantiles.

A density version of the above condition which is more natural to use in applications involving predictive density comparison follows immediately, and can be written as

$$\begin{aligned} & E \left( \left( \left( F_1(\bar{u}|Z^t, \theta_1^\dagger) - F_1(\underline{u}|Z^t, \theta_1^\dagger) \right) - \left( F_0(\bar{u}|Z^t, \theta_0) - F_0(\underline{u}|Z^t, \theta_0) \right) \right)^2 \right. \\ & \quad \left. - \left( \left( F_2(\bar{u}|Z^t, \theta_2^\dagger) - F_2(\underline{u}|Z^t, \theta_2^\dagger) \right) - \left( F_0(\bar{u}|Z^t, \theta_0) - F_0(\underline{u}|Z^t, \theta_0) \right) \right)^2 \right) \leq 0. \end{aligned}$$

### 5.2.2 The Tests Statistic and Its Asymptotic Behavior

In this section,  $F_1(\cdot|Z^t, \theta_1^\dagger)$  is taken as the benchmark model, and the objective is to test whether some competitor model can provide a more accurate approximation of  $F_0(\cdot|Z^t, \theta_0)$  than the benchmark. The null

and the alternative hypotheses are:

$$H_0 : \max_{k=2,\dots,m} \int_U E \left( \left( F_1(u|Z^t, \theta_1^\dagger) - F_0(u|Z^t, \theta_0) \right)^2 - \left( F_k(u|Z^t, \theta_k^\dagger) - F_0(u|Z^t, \theta_0) \right)^2 \right) \phi(u) du \leq 0 \quad (60)$$

versus

$$H_A : \max_{k=2,\dots,m} \int_U E \left( \left( F_1(u|Z^t, \theta_1^\dagger) - F_0(u|Z^t, \theta_0) \right)^2 - \left( F_k(u|Z^t, \theta_k^\dagger) - F_0(u|Z^t, \theta_0) \right)^2 \right) \phi(u) du > 0, \quad (61)$$

where  $\phi(u) \geq 0$  and  $\int_U \phi(u) = 1$ ,  $u \in U \subset \Re$ ,  $U$  possibly unbounded. Note that for a given  $u$ , we compare conditional distributions in terms of their (mean square) distance from the true distribution. We then average over  $U$ . As discussed above, a possibly more natural version of the above hypotheses which is appropriate if interest focuses on conditional confidence intervals, so that the objective is to “approximate”  $\Pr(\underline{u} \leq Y_t \leq \bar{u}|Z^t)$ , and hence to evaluate a region of the predictive density, then the null and alternative hypotheses can be stated as:

$$\begin{aligned} H'_0 : \max_{k=2,\dots,m} E & \left( \left( \left( F_1(\bar{u}|Z^t, \theta_1^\dagger) - F_1(\underline{u}|Z^t, \theta_1^\dagger) \right) - \left( F_0(\bar{u}|Z^t, \theta_0) - F_0(\underline{u}|Z^t, \theta_0) \right) \right)^2 \right. \\ & \left. - \left( \left( F_k(\bar{u}|Z^t, \theta_k^\dagger) - F_k(\underline{u}|Z^t, \theta_k^\dagger) \right) - \left( F_0(\bar{u}|Z^t, \theta_0) - F_0(\underline{u}|Z^t, \theta_0) \right) \right)^2 \right) \leq 0. \end{aligned}$$

versus

$$\begin{aligned} H'_A : \max_{k=2,\dots,m} E & \left( \left( \left( F_1(\bar{u}|Z^t, \theta_1^\dagger) - F_1(\underline{u}|Z^t, \theta_1^\dagger) \right) - \left( F_0(\bar{u}|Z^t, \theta_0) - F_0(\underline{u}|Z^t, \theta_0) \right) \right)^2 \right. \\ & \left. - \left( \left( F_k(\bar{u}|Z^t, \theta_k^\dagger) - F_k(\underline{u}|Z^t, \theta_k^\dagger) \right) - \left( F_0(\bar{u}|Z^t, \theta_0) - F_0(\underline{u}|Z^t, \theta_0) \right) \right)^2 \right) > 0. \end{aligned}$$

Alternatively, if interest focuses on testing the null of equal accuracy of two conditional distribution models, say  $F_1$  and  $F_k$ , we can simply state the hypotheses as:

$$H''_0 : \int_U E \left( \left( F_1(u|Z^t, \theta_1^\dagger) - F_0(u|Z^t, \theta_0) \right)^2 - \left( F_k(u|Z^t, \theta_k^\dagger) - F_0(u|Z^t, \theta_0) \right)^2 \right) \phi(u) du = 0$$

versus

$$H''_A : \int_U E \left( \left( F_1(u|Z^t, \theta_1^\dagger) - F_0(u|Z^t, \theta_0) \right)^2 - \left( F_k(u|Z^t, \theta_k^\dagger) - F_0(u|Z^t, \theta_0) \right)^2 \right) \phi(u) du \neq 0,$$

or we can write the predictive density (interval) version of these hypotheses. Given that results for all of these cases are discussed in Corradi and Swanson (2003c,d), and given that the same bootstrap approach to construction of valid critical values can be used to for any set of hypotheses outlined above, we shall only recap the case of testing  $H_0$  against  $H_A$ . The reader is referred to the two cited papers for further details.

Needless to say, we do not know  $F_0(u|Z^t)$ . However, it is easy to see that

$$\begin{aligned} & E \left( \left( F_1(u|Z^t, \theta_1^\dagger) - F_0(u|Z^t, \theta_0) \right)^2 - \left( F_k(u|Z^t, \theta_k^\dagger) - F_0(u|Z^t, \theta_0) \right)^2 \right) \\ = & E \left( \left( 1\{Y_t \leq u\} - F_1(u|Z^t, \theta_1^\dagger) \right)^2 \right) - E \left( \left( 1\{Y_t \leq u\} - F_k(u|Z^t, \theta_k^\dagger) \right)^2 \right), \end{aligned} \quad (62)$$

where the RHS of (62) does not require the knowledge of the true conditional distribution.

The intuition behind equation (62) is very simple. First, note that for any given  $u$ ,  $E(1\{Y_t \leq u\}|Z^t) = \Pr(Y_t \leq u|Z^t) = F_0(u|Z^t, \theta_0)$ . Thus,  $1\{Y_t \leq u\} - F_k(u|Z^t, \theta_k^\dagger)$  can be interpreted as an “error” term associated with computation of the conditional expectation under  $F_i$ . Now,  $j = 1, \dots, m$ :

$$\begin{aligned} \mu_k^2(u) &= E \left( \left( 1\{Y_t \leq u\} - F_k(u|Z^t, \theta_k^\dagger) \right)^2 \right) \\ &= E \left( \left( (1\{Y_t \leq u\} - F_0(u|Z^t, \theta_0)) - (F_k(u|Z^t, \theta_k^\dagger) - F_0(u|Z^t, \theta_0)) \right)^2 \right) \\ &= E((1\{Y_t \leq u\} - F_0(u|Z^t, \theta_0))^2) + E \left( \left( F_k(u|Z^t, \theta_k^\dagger) - F_0(u|Z^t, \theta_0) \right)^2 \right), \end{aligned}$$

given that the expectation of the cross product is zero (which follows because  $1\{Y_t \leq u\} - F_0(u|Z^t, \theta_0)$  is uncorrelated with any measurable function of  $Z^t$ ). Therefore,

$$\mu_1^2(u) - \mu_k^2(u) = E \left( \left( F_1(u|Z^t, \theta_1^\dagger) - F_0(u|Z^t, \theta_0) \right)^2 \right) - E \left( \left( F_k(u|Z^t, \theta_k^\dagger) - F_0(u|Z^t, \theta_0) \right)^2 \right). \quad (63)$$

The statistic of interest is

$$Z_{P,j} = \max_{k=2, \dots, m} \int_U Z_{P,u,j}(1, k) \phi(u) du, \quad j = 1, 2 \quad (64)$$

where for  $j = 1$  (rolling estimation scheme),

$$Z_{P,u,1}(1, k) = \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( \left( 1\{y_{t+1} \leq u\} - F_1(u|Z^t, \hat{\theta}_{1,t,R}) \right)^2 - \left( 1\{y_{t+1} \leq u\} - F_k(u|Z^t, \hat{\theta}_{k,t,R}) \right)^2 \right) \quad (65)$$

and for  $j = 2$  (recursive estimation scheme),

$$Z_{P,u,2}(1, k) = \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( \left( 1\{y_{t+1} \leq u\} - F_1(u|Z^t, \hat{\theta}_{1,t}) \right)^2 - \left( 1\{y_{t+1} \leq u\} - F_k(u|Z^t, \hat{\theta}_{k,t}) \right)^2 \right), \quad (66)$$

where  $\hat{\theta}_{i,t,R}$  and  $\hat{\theta}_{i,t}$  are defined as in (20) and in (19) in Section 3.1.

As shown above and in Corradi and Swanson (2003c), the hypotheses of interest can be restated as:

$$H_0 : \max_{k=2, \dots, m} \int_U (\mu_1^2(u) - \mu_k^2(u)) \phi(u) du \leq 0$$

versus

$$H_A : \max_{k=2,\dots,m} \int_U (\mu_1^2(u) - \mu_k^2(u)) \phi(u) du > 0,$$

where  $\mu_i^2(u) = E \left( \left( 1\{y_t \leq u\} - F_i(u|Z^t, \theta_i^\dagger) \right)^2 \right)$ . In the sequel, we require:

**MD1:**  $(y_t, X_t)$ , with  $y_t$  scalar and  $X_t$  an  $R^\zeta$ -valued ( $0 < \zeta < \infty$ ) vector, is a strictly stationary and absolutely regular  $\beta$ -mixing process with size  $-4(4 + \psi)/\psi$ ,  $\psi > 0$ .

**MD2:** (i)  $\theta_i^\dagger$  is uniquely identified (i.e.  $E(\ln f_i(y_t, Z^{t-1}, \theta_i)) < E(\ln f_i(y_t, Z^{t-1}, \theta_i^\dagger))$  for any  $\theta_i \neq \theta_i^\dagger$ ); (ii)  $\ln f_i$  is twice continuously differentiable on the interior of  $\Theta_i$ , for  $i = 1, \dots, m$ , and for  $\Theta_i$  a compact subset of  $R^{\varrho(i)}$ ; (iii) the elements of  $\nabla_{\theta_i} \ln f_i$  and  $\nabla_{\theta_i}^2 \ln f_i$  are  $p$ -dominated on  $\Theta_i$ , with  $p > 2(2 + \psi)$ , where  $\psi$  is the same positive constant as defined in Assumption A1; and (iii)  $E(-\nabla_{\theta_i}^2 \ln f_i(\theta_i))$  is positive definite uniformly on  $\Theta_i$ .

**MD3:**  $T = R + P$ , and as  $T \rightarrow \infty$ ,  $P/R \rightarrow \pi$ , with  $0 < \pi < \infty$ .

**MD4:** (i)  $F_i(u|Z^t, \theta_i)$  is continuously differentiable on the interior of  $\Theta_i$  and  $\nabla_{\theta_i} F_i(u|Z^t, \theta_i^\dagger)$  is  $2r$ -dominated on  $\Theta_i$ , uniformly in  $u$ ,  $r > 2$ ,  $i = 1, \dots, m$ <sup>24</sup> and (ii) let  $v_{kk}(u) = \text{plim}_{T \rightarrow \infty}$   
 $Var \left( \frac{1}{\sqrt{T}} \sum_{t=s}^T \left( \left( \left( 1\{y_{t+1} \leq u\} - F_1(u|Z^t, \theta_1^\dagger) \right)^2 - \mu_1^2(u) \right) - \left( \left( 1\{y_{t+1} \leq u\} - F_k(u|Z^t, \theta_k^\dagger) \right)^2 - \mu_k^2(u) \right) \right) \right)$ ,  
 $k = 2, \dots, m$ , define analogous covariance terms,  $v_{j,k}(u)$ ,  $j, k = 2, \dots, m$ , and assume that  $[v_{j,k}(u)]$  is positive semi-definite, uniformly in  $u$ .

Assumptions **MD1** and **MD2** are standard memory, moment, smoothness and identifiability conditions. **MD1** requires  $(y_t, X_t)$  to be strictly stationary and absolutely regular. The memory condition is stronger than  $\alpha$ -mixing, but weaker than (uniform)  $\phi$ -mixing. Assumption **MD3** requires that  $R$  and  $P$  grow at the same rate. Of course, if  $R$  grows faster than  $P$ , then parameter estimation error vanishes in probability (as discussed above), and there is no need to capture the contribution of parameter estimation error when constructing bootstrap critical values. Assumptions **MD4(i)** states standard smoothness and domination conditions imposed on the conditional distributions of the models, and assumption **MD4(ii)** states that at least one of the competing models,  $F_2(\cdot| \cdot, \theta_1^\dagger), \dots, F_n(\cdot| \cdot, \theta_n^\dagger)$ , has to be nonnested with (and non nesting) the benchmark.

**Proposition 4.9 (from Proposition 1 in Corradi and Swanson (2003c)):** Let **MD1-MD4** hold.

Then,

$$\max_{k=2,\dots,n} \int_U \left( Z_{P,u,j}(1, k) - \sqrt{P} (\mu_1^2(u) - \mu_k^2(u)) \right) \phi_U(u) du \xrightarrow{d} \max_{k=2,\dots,n} \int_U Z_{1,k,j}(u) \phi_U(u) du,$$

---

<sup>24</sup>We require that for  $j = 1, \dots, p_i$ ,  $\left( E \left( \nabla_\theta F_i(u|Z^t, \theta_i^\dagger) \right) \right)_j \leq D_t(u)$ , with  $\sup_t \sup_{u \in \mathfrak{R}} E(D_t(u)^{2r}) < \infty$ .

where  $Z_{1,k,j}(u)$  is a zero mean Gaussian process with covariance  $C_{k,j}(u, u')$  ( $j = 1$  corresponds to rolling and  $j = 2$  to recursive estimation schemes), equal to:

$$\begin{aligned}
& E \left( \sum_{j=-\infty}^{\infty} \left( \left( 1\{y_{s+1} \leq u\} - F_1(u|Z^s, \theta_1^\dagger) \right)^2 - \mu_1^2(u) \right) \left( \left( 1\{y_{s+j+1} \leq u'\} - F_1(u'|Z^{s+j}, \theta_1^\dagger) \right)^2 - \mu_1^2(u') \right) \right) \\
& + E \left( \sum_{j=-\infty}^{\infty} \left( \left( 1\{y_{s+1} \leq u\} - F_k(u|Z^s, \theta_k^\dagger) \right)^2 - \mu_k^2(u) \right) \left( \left( 1\{y_{s+j+1} \leq u'\} - F_k(u'|Z^{s+j}, \theta_k^\dagger) \right)^2 - \mu_k^2(u') \right) \right) \\
& - 2E \left( \sum_{j=-\infty}^{\infty} \left( \left( 1\{y_{s+1} \leq u\} - F_1(u|Z^s, \theta_1^\dagger) \right)^2 - \mu_1^2(u) \right) \left( \left( 1\{y_{s+j+1} \leq u'\} - F_k(u'|Z^{s+j}, \theta_k^\dagger) \right)^2 - \mu_k^2(u') \right) \right) \\
& + 4\Pi_j m_{\theta_1^\dagger}(u)' A(\theta_1^\dagger) E \left( \sum_{j=-\infty}^{\infty} \nabla_{\theta_1} \ln f_1(y_{s+1}|Z^s, \theta_1^\dagger) \nabla_{\theta_1} \ln f_1(y_{s+j+1}|Z^{s+j}, \theta_1^\dagger)' \right) A(\theta_1^\dagger) m_{\theta_1^\dagger}(u') \\
& + 4\Pi_j m_{\theta_k^\dagger}(u)' A(\theta_k^\dagger) E \left( \sum_{j=-\infty}^{\infty} \nabla_{\theta_k} \ln f_k(y_{s+1}|Z^s, \theta_k^\dagger) \nabla_{\theta_k} \ln f_k(y_{s+j+1}|Z^{s+j}, \theta_k^\dagger)' \right) A(\theta_k^\dagger) m_{\theta_k^\dagger}(u') \\
& - 4\Pi_j m_{\theta_1^\dagger}(u)' A(\theta_1^\dagger) E \left( \sum_{j=-\infty}^{\infty} \nabla_{\theta_1} \ln f_1(y_{s+1}|Z^s, \theta_1^\dagger) \nabla_{\theta_k} \ln f_k(y_{s+j+1}|Z^{s+j}, \theta_k^\dagger)' \right) A(\theta_k^\dagger) m_{\theta_k^\dagger}(u') \\
& - 4C\Pi_j m_{\theta_1^\dagger}(u)' A(\theta_1^\dagger) E \left( \sum_{j=-\infty}^{\infty} \nabla_{\theta_1} \ln f_1(y_{s+1}|Z^s, \theta_1^\dagger) \left( \left( 1\{y_{s+j+1} \leq u\} - F_1(u|Z^{s+j}, \theta_1^\dagger) \right)^2 - \mu_1^2(u) \right) \right) \\
& + 4C\Pi_j m_{\theta_1^\dagger}(u)' A(\theta_1^\dagger) E \left( \sum_{j=-\infty}^{\infty} \nabla_{\theta_1} \ln f_1(y_{s+1}|Z^s, \theta_1^\dagger) \left( \left( 1\{y_{s+j+1} \leq u\} - F_k(u|Z^{s+j}, \theta_k^\dagger) \right)^2 - \mu_k^2(u) \right) \right) \\
& - 4C\Pi_j m_{\theta_k^\dagger}(u)' A(\theta_k^\dagger) E \left( \sum_{j=-\infty}^{\infty} \nabla_{\theta_k} \ln f_k(y_{s+1}|Z^s, \theta_k^\dagger)' \left( \left( 1\{y_{s+j+1} \leq u\} - F_k(u|Z^{s+j}, \theta_k^\dagger) \right)^2 - \mu_k^2(u) \right) \right) \\
& + 4C\Pi_j m_{\theta_k^\dagger}(u)' A(\theta_k^\dagger) E \left( \sum_{j=-\infty}^{\infty} \nabla_{\theta_k} \ln f_k(y_{s+1}|Z^s, \theta_k^\dagger)' \left( \left( 1\{y_{s+j+1} \leq u\} - F_1(u|Z^{s+j}, \theta_1^\dagger) \right)^2 - \mu_1^2(u) \right) \right), \tag{67}
\end{aligned}$$

with  $m_{\theta_i^\dagger}(u)' = E \left( \nabla_{\theta_i} F_i(u|Z^t, \theta_i^\dagger)' \left( 1\{y_{t+1} \leq u\} - F_i(u|Z^t, \theta_i^\dagger) \right) \right)$  and  $A(\theta_i^\dagger) = A_i^\dagger = \left( E \left( -\nabla_{\theta_i}^2 \ln f_i(y_{t+1}|Z^t, \theta_i^\dagger) \right) \right)^{-1}$ , and for  $j = 1$  and  $P \leq R$ ,  $\Pi_1 = \left( \pi - \frac{\pi^2}{3} \right)$ ,  $C\Pi_1 = \frac{\pi}{2}$ , and for  $P > R$ ,  $\Pi_1 = \left( 1 - \frac{1}{3\pi} \right)$  and  $C\Pi_1 = \left( 1 - \frac{1}{2\pi} \right)$ . Finally, for  $j = 2$ ,  $\Pi_2 = 2 \left( 1 - \pi^{-1} \ln(1 + \pi) \right)$  and  $C\Pi_2 = 0.5\Pi_2$ .

From this proposition, note that when all competing models provide an approximation to the true conditional distribution that is as (mean square) accurate as that provided by the benchmark (i.e. when  $\int_U (\mu_1^2(u) - \mu_k^2(u)) \phi(u) du = 0, \forall k$ ), then the limiting distribution is a zero mean Gaussian process with a covariance kernel which is not nuisance parameter free. Additionally, when all competitor models are worse than the benchmark, the statistic diverges to minus infinity at rate  $\sqrt{P}$ . Finally, when only some competitor models are worse than the benchmark, the limiting distribution provides a conservative test, as  $Z_P$  will always be smaller than  $\max_{k=2,\dots,m} \int_U (Z_{P,u}(1,k) - \sqrt{P}(\mu_1^2(u) - \mu_k^2(u))) \phi(u) du$ , asymptotically. Of course, when  $H_A$  holds, the statistic diverges to plus infinity at rate  $\sqrt{P}$ .

### 5.2.3 Bootstrap Critical Values for the Density Accuracy Test

Turning now to the construction of critical values for the above test, note that using the bootstrap sampling procedures defined in Sections 3.4.1 and 3.5.1 or in Sections 3.4.2 and 3.5.2, one first constructs appropriate bootstrap samples. Thereafter, form bootstrap statistics as follows

$$Z_{P,j}^* = \max_{k=2,\dots,n} \int_U Z_{P,u,j}^*(1,k) \phi(u) du,$$

where for  $j = 1$  (rolling estimation scheme) and  $P \leq R$ ,

$$\begin{aligned} Z_{P,u,1}^*(1,k) &= \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( \left( \left( 1\{y_{t+1}^* \leq u\} - F_1(u|Z^{*,t}, \hat{\theta}_{1,t,R}^*) \right)^2 - \left( 1\{y_{t+1} \leq u\} - F_1(u|Z^t, \hat{\theta}_{1,t,R}) \right)^2 \right) \right. \\ &\quad \left. - \left( \left( 1\{y_{t+1}^* \leq u\} - F_k(u|Z^{*,t}, \hat{\theta}_{k,t,R}^*) \right)^2 - \left( 1\{y_{t+1} \leq u\} - F_k(u|Z^t, \hat{\theta}_{k,t,R}) \right)^2 \right) \right) \\ &\quad - \frac{2}{T} \sum_{t=s}^{T-1} \left( \nabla_{\theta_1} F_1(u|Z^t, \hat{\theta}_{1,T}) \left( 1\{y_{t+1}^* \leq u\} - F_1(u|Z^t, \hat{\theta}_{1,T}) \right) \right)' \\ &\quad \times \left( \Psi_{R,P,1}^{*(1)} - \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( \hat{\theta}_{1,t,R}^* - \hat{\theta}_{1,t,R} \right) \right) \\ &\quad + \frac{2}{T} \sum_{t=s}^{T-1} \left( \nabla_{\theta_k} F_k(u|Z^t, \hat{\theta}_{k,T})' \left( 1\{y_{t+1}^* \leq u\} - F_k(u|Z^t, \hat{\theta}_{k,T}) \right) \right) \\ &\quad \times \left( \Psi_{R,P,1}^{*(k)} - \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( \hat{\theta}_{k,t,R}^* - \hat{\theta}_{k,t,R} \right) \right). \end{aligned} \tag{68}$$

For  $j = 1$  and  $P > R$ ,  $Z_{P,u,1}^*(1,k)$  is defined as above, but with  $\Psi_{R,P,1}^{*(1)}, \Psi_{R,P,1}^{*(k)}$  replaced by  $\Psi_{R,P,2}^{*(1)}, \Psi_{R,P,2}^{*(k)}$ .

For  $j = 2$  (recursive estimation scheme),

$$\begin{aligned}
Z_{P,u,2}^*(1,k) &= \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( \left( \left( 1\{y_{t+1}^* \leq u\} - F_1(u|Z^{*,t}, \hat{\theta}_{1,t}^*) \right)^2 - \left( 1\{y_{t+1} \leq u\} - F_1(u|Z^t, \hat{\theta}_{1,t}) \right)^2 \right) \right. \\
&\quad \left. - \left( \left( 1\{y_{t+1}^* \leq u\} - F_k(u|Z^{*,t}, \hat{\theta}_{k,t}^*) \right)^2 - \left( 1\{y_{t+1} \leq u\} - F_k(u|Z^t, \hat{\theta}_{k,t}) \right)^2 \right) \right) \\
&\quad - \frac{2}{T} \sum_{t=s}^{T-1} \left( \nabla_{\theta_1} F_1(u|Z^t, \hat{\theta}_{1,T})' \left( 1\{y_{t+1}^* \leq u\} - F_1(u|Z^t, \hat{\theta}_{1,T}) \right) \right)' \\
&\quad \times \left( \Psi_{R,P,3}^{*(1)} - \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( \hat{\theta}_{1,t}^* - \hat{\theta}_{1,t} \right) \right) \\
&\quad + \frac{2}{T} \sum_{t=s}^{T-1} \left( \nabla_{\theta_k} F_k(u|Z^t, \hat{\theta}_{k,T})' \left( 1\{y_{t+1}^* \leq u\} - F_k(u|Z^t, \hat{\theta}_{k,T}) \right) \right)' \\
&\quad \times \left( \Psi_{R,P,3}^{*(k)} - \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( \hat{\theta}_{k,t}^* - \hat{\theta}_{k,t} \right) \right).
\end{aligned}$$

The following result then holds.

**Proposition 4.10 (from Proposition 2 in Corradi and Swanson (2003c)):** Let **MD1-MD4** hold.

Also, assume that: (i) for the rolling estimation scheme and  $P \leq R$ , as  $P \rightarrow \infty$  and  $l_1 \rightarrow \infty$ ,  $l_1/P^{1/4} \rightarrow 0$ , and as  $R \rightarrow \infty$  and  $l_3 \rightarrow \infty$ ,  $l_3/P^{1/4} \rightarrow 0$ , and finally as  $R - P \rightarrow \infty$  and  $l_2 \rightarrow \infty$ ,  $l_2/(R - P)^{1/4} \rightarrow 0$ ; or (ii) for the rolling estimation scheme and  $P > R$ , as  $R \rightarrow \infty$  and  $l_1 \rightarrow \infty$ ,  $l_1/R^{1/4} \rightarrow 0$ , and as  $P \rightarrow \infty$  and  $l_3 \rightarrow \infty$ ,  $l_3/R^{1/4} \rightarrow 0$ , and finally as  $P - R \rightarrow \infty$  and  $l_2 \rightarrow \infty$ ,  $l_2/(P - R)^{1/4} \rightarrow 0$ , or (iii) for the recursive estimation scheme, as  $P, R \rightarrow \infty$  and  $l_1, l_2 \rightarrow \infty$ , then  $\frac{l_2}{P^{1/4}} \rightarrow 0$  and  $\frac{l_1}{R^{1/4}} \rightarrow 0$ . Then, as  $P$  and  $R \rightarrow \infty$ , for  $j = 1, 2$

$$P \left( \omega : \sup_{v \in \Re} \left| P_{R,P}^* \left( \max_{k=2,\dots,n} \int_U Z_{P,u,j}^*(1,k) \phi(u) du \leq v \right) - P \left( \max_{k=2,\dots,n} \int_U Z_{P,u,j}^\mu(1,k) \phi(u) du \leq v \right) \right| > \varepsilon \right) \rightarrow 0,$$

where  $Z_{P,u,j}^\mu(1,k) = Z_{P,u,j}(1,k) - \sqrt{P} (\mu_1^2(u) - \mu_k^2(u))$ .

The above result suggests proceeding in the following manner. For any bootstrap replication, compute the bootstrap statistic,  $Z_{P,j}^*$ . Perform  $B$  bootstrap replications ( $B$  large) and compute the quantiles of the empirical distribution of the  $B$  bootstrap statistics. Reject  $H_0$ , if  $Z_{P,j}$  is greater than the  $(1-\alpha)$ th-percentile. Otherwise, do not reject. Now, for all samples except a set with probability measure approaching zero,  $Z_{P,j}$  has the same limiting distribution as the corresponding bootstrapped statistic when  $E(\mu_1^2(u) - \mu_k^2(u)) = 0$ ,  $\forall k$ , ensuring asymptotic size equal to  $\alpha$ . On the other hand, when one or more competitor models are strictly dominated by the benchmark, the rule provides a test with asymptotic size between 0 and  $\alpha$ . Under the alternative,  $Z_{P,j}$  diverges to (plus) infinity, while the corresponding bootstrap statistic has a well defined limiting distribution, ensuring unit asymptotic power. From the above discussion, we see that the

bootstrap distribution provides correct asymptotic critical values only for the least favorable case under the null hypothesis; that is, when all competitor models are as good as the benchmark model. When  $\max_{k=2,\dots,m} \int_U (\mu_1^2(u) - \mu_k^2(u)) \phi(u) du = 0$ , but  $\int_U (\mu_1^2(u) - \mu_k^2(u)) \phi(u) du < 0$  for some  $k$ , then the bootstrap critical values lead to conservative inference.

An alternative to our bootstrap critical values in this case is the construction of critical values based on subsampling (see above discussion). Heuristically, construct  $T - 2b_T$  statistics using subsamples of length  $b_T$ , where  $b_T/T \rightarrow 0$ . The empirical distribution of these statistics computed over the various subsamples properly mimics the distribution of the statistic. Thus, subsampling provides valid critical values even for the case where  $\max_{k=2,\dots,m} \int_U (\mu_1^2(u) - \mu_k^2(u)) \phi(u) du = 0$ , but  $\int_U (\mu_1^2(u) - \mu_k^2(u)) \phi(u) du < 0$  for some  $k$ . This is the approach used by Linton, Maasoumi and Whang (2004), for example, in the context of testing for stochastic dominance. An alternative approach for addressing the conservative nature of our bootstrap critical values which is also discussed above is the method of Hansen (2004).

# Part IV: Appendix and References

## 6 Appendix

### Proof of Proposition 3.2:

For brevity, we just consider the case of recursive estimation. The case of rolling estimation scheme can be treated in an analogous way.

$$\begin{aligned}
\widehat{W}_{P,rec} &= \frac{1}{\sqrt{P}} \sum_{t=R+1}^T \left( 1\{F_t(y_t|Z^{t-1}, \widehat{\theta}_t) \leq r\} - r \right) \\
&= \frac{1}{\sqrt{P}} \sum_{t=R+1}^T \left( 1\{F_t(y_t|Z^{t-1}, \theta_0) \leq F(F^{-1}(r|Z^{t-1}, \widehat{\theta}_t)|Z^{t-1}, \theta_0)\} - r \right) \\
&= \frac{1}{\sqrt{P}} \sum_{t=R+1}^T \left( 1\{F_t(y_t|Z^{t-1}, \theta_0) \leq F(F^{-1}(r|Z^{t-1}, \widehat{\theta}_t)|Z^{t-1}, \theta_0)\} - F(F^{-1}(r|Z^{t-1}, \widehat{\theta}_t)|Z^{t-1}, \theta_0) \right) \\
&\quad + \frac{1}{\sqrt{P}} \sum_{t=R+1}^T \left( F(F^{-1}(r|Z^{t-1}, \bar{\theta}_t)|Z^{t-1}, \theta_0) - r \right) \\
&= I_P + II_P
\end{aligned}$$

We first want to show that:

- (i)  $I_P = \frac{1}{\sqrt{P}} \sum_{t=R+1}^T (1\{F_t(y_t|Z^{t-1}, \theta_0) \leq r\} - r) + o_P(1)$ , uniformly in  $r$
- (ii)  $II_P = \bar{g}(r) \frac{1}{\sqrt{P}} \sum_{t=R+1}^T (\widehat{\theta}_t - \theta_0) + o_P(1)$ , uniformly in  $r$ .

Given BAI2, (ii) follows immediately. As for (i), need to show that

$$\begin{aligned}
&\frac{1}{\sqrt{P}} \sum_{t=R+1}^T \left( 1 \left\{ F_t(y_t|Z^{t-1}, \theta_0) \leq r + \frac{\partial F_t}{\partial \theta} (F_t^{-1}(r|\bar{\theta}_t), \theta_0) (\widehat{\theta}_t - \theta_0) \right\} - \left( r + \frac{\partial F_t}{\partial \theta} (F_t^{-1}(r|\bar{\theta}_t), \theta_0) (\widehat{\theta}_t - \theta_0) \right) \right) \\
&= \frac{1}{\sqrt{P}} \sum_{t=R+1}^T (1\{F_t(y_t|\Omega_{t-1}, \theta_0) \leq r\} - r) + o_P(1), \text{ uniformly in } r
\end{aligned}$$

Given BAI3', the equality above follows by the same argument as in the proof of Theorem 1 in Bai. Given

(i) and (ii), it follows that

$$\widehat{V}_{P,rec} = \frac{1}{\sqrt{P}} \sum_{t=R+1}^T (1\{F_t(y_t|\Omega_{t-1}, \theta_0) \leq r\} - r) + \bar{g}(r) \frac{1}{\sqrt{P}} \sum_{t=R+1}^T (\widehat{\theta}_t - \theta_0) + o_P(1), \quad (69)$$

uniformly in  $r$ , where  $\bar{g}(r) = \text{plim} \frac{1}{P} \sum_{t=R+1}^T \frac{\partial F_t}{\partial \theta} (F_t^{-1}(r|\bar{\theta}_t), \theta_0)$ ,  $\bar{\theta}_t \in (\widehat{\theta}_t, \theta_0)$ .

The desired outcome, follows if the martingalization argument applies also in the recursive estimation case and the parameter estimation error component cancel out in the statistic. Now, equation A4 in Bai (2003) holds in the form of eq.(69) above. Also,

$$\widehat{W}_{P,rol}(r) = \widehat{V}_{P,rol}(r) - \int_0^r \left( \dot{g}(s) C^{-1}(s) \dot{g}(s)' \int_s^1 \dot{g}(\tau) d\widehat{V}_{P,rol}(\tau) \right) ds \quad (70)$$

It remain to see that the parameter estimation error term, which enters both in  $\widehat{V}_{P,rol}(r)$  and in  $d\widehat{V}_{P,rol}(\tau)$  cancels out, as in the fixed estimation scheme.

We notice that  $g(r)$  is defined as in the fixed scheme case. Now, it suffices to define the term  $c$ , at the bottom of p.543 (below equation A6 in Bai),  $c$  as:

$$c = \frac{1}{\sqrt{P}} \sum_{t=R+1}^T (\widehat{\theta}_t - \theta_0).$$

Then, the same argument used by Bai at p.544 applies here, and the term  $\frac{1}{\sqrt{P}} \sum_{t=R+1}^T (\widehat{\theta}_t - \theta_0)$  is cancelled out from the RHS in (70).

**Proof of Proposition 3.4:** (i) We begin by consider the case of recursive estimation. Given CS1 and CS3,  $\widehat{\theta}_t \xrightarrow{a.s.} \theta^\dagger$ , with  $\theta^\dagger = \theta_0$ , under  $H_0$ . We Given A2(i), and following Bai (2003, p.545-546), we have,

$$\begin{aligned} \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (1\{F(y_{t+1}|Z^t, \widehat{\theta}_t) \leq r\} - r) &= \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( 1\{F(y_{t+1}|Z^t, \theta_0) \leq F(F^{-1}(r|Z^t, \widehat{\theta}_t)|Z^t, \theta_0)\} - r \right) \\ &= \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \left( 1\{F(y_{t+1}|Z^t, \theta_0) \leq F(F^{-1}(r|Z^t, \widehat{\theta}_t)|Z^t, \theta_0)\} - F(F^{-1}(r|Z^t, \widehat{\theta}_t)|Z^t, \theta_0) \right) \\ &\quad - \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \nabla_\theta F(F^{-1}(r|Z^t, \bar{\theta}_t)|Z^t, \theta_0)(\widehat{\theta}_t - \theta_0) \end{aligned} \quad (71)$$

with  $\bar{\theta}_t \in (\widehat{\theta}_t, \theta_0)$ . Given CS1 and CS3,  $(\widehat{\theta}_t - \theta_0) = O_P(1)$ , uniformly in  $t$ , thus the first term on the RHS of (71) can be treated by the same argument as in the proof of Theorem 1 in Corradi and Swanson (2003a). As for the last term on the RHS of (71), by the uniform law of large numbers for mixing processes.

$$\begin{aligned} &\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} \nabla_\theta F(F^{-1}(r|Z^t, \bar{\theta}_t)|Z^t, \theta_0)(\widehat{\theta}_t - \theta_0) \\ &= E(\nabla_\theta F(x(r)|Z^{t-1}, \theta_0))' \frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\widehat{\theta}_t - \theta_0) + o_P(1), \end{aligned} \quad (72)$$

where the  $o_P(1)$  term is uniform in  $r$ . The limiting distribution of  $\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\widehat{\theta}_t - \theta_0)$ , and so the key contribution of parameter estimation error comes from Theorem 4.1 and Lemma 4.1 in West (1996). As for

the rolling case, the same argument as above applies, with  $\widehat{\theta}_t$  replaced by  $\widehat{\theta}_{t,R}$ . The limiting distribution of  $\frac{1}{\sqrt{P}} \sum_{t=R}^{T-1} (\widehat{\theta}_t - \theta_0)$  is given by Lemma 4.1 and 4.2 in West and McCracken (1998).

**Proof of Proposition 3.5:** Straightforward, combining the proof of Theorem 2 in Corradi and Swanson (2003a) and the proof of Proposition 3.4.

**Proof of Proposition 3.7: to be completed ...**

**Proof of Proposition 3.8:**

**Proof of Proposition 3.10:**

**Proof of Proposition 3.11:**

**Proof of Proposition 4.5 (ii):** Via a mean value expansion, and given A1,A2

$$\begin{aligned}
S_P(1, k) &= \frac{1}{P^{1/2}} \sum_{t=R}^{T-1} (g(\widehat{u}_{1,t+1}) - g(\widehat{u}_{k,t+1})) \\
&= \frac{1}{P^{1/2}} \sum_{t=R}^{T-1} (g(u_{1,t+1}) - g(u_{k,t+1})) \\
&\quad + \frac{1}{P} \sum_{t=R}^{T-1} g'(\bar{u}_{1,t+1}) \nabla_{\theta_1} \kappa_1(Z^t, \bar{\theta}_{1,t}) P^{1/2} (\widehat{\theta}_{1,t} - \theta_1^\dagger) \\
&\quad - \frac{1}{P} \sum_{t=R}^{T-1} g'(\bar{u}_{k,t+1}) \nabla_{\theta_k} \kappa_k(Z^t, \bar{\theta}_{k,t}) P^{1/2} (\widehat{\theta}_{k,t} - \theta_k^\dagger) \\
&= \frac{1}{P^{1/2}} \sum_{t=R}^{T-1} (g(u_{1,t+1}) - g(u_{k,t+1})) \\
&\quad + \mu_1 \frac{1}{P^{1/2}} \sum_{t=R}^{T-1} (\widehat{\theta}_{1,t} - \theta_1^\dagger) - \mu_k \frac{1}{P^{1/2}} \sum_{t=R}^{T-1} (\widehat{\theta}_{k,t} - \theta_k^\dagger) + o_P(1),
\end{aligned}$$

where  $\mu_1 = E(g'(u_{1,t+1}) \nabla_{\theta_1} \kappa_1(Z^t, \theta_1^\dagger))$ , and  $\mu_k$  is defined analogously. Now, when all competitors have the same predictive accuracy as the benchmark model, by the same argument as in Theorem 4.1 in West (1996),

$$(S_P(1, 2), \dots, S_P(1, n)) \xrightarrow{d} N(0, V),$$

where  $V$  is a  $n \times n$  matrix with  $i, j$  element  $v_{i,j} = S_{g_i g_j} + 2\Pi C_{ii} + 2\Pi C_{jj} - 2\Pi C_{ij}$ , where  $C_{ij} = \sum_{j=-\infty}^{\infty} E \left( \left( \nabla_{\theta} q_i(y_{1+s}, Z^s, \theta_i^\dagger) \right) \left( \nabla_{\theta} q_j(y_{1+s+j}, Z^{s+j}, \theta_j^\dagger) \right)' \right)$ ,  $\Pi = 1 - \pi^{-1} \ln(1 + \pi)$ . The distribution of  $S_P$  then follows straightforwardly from the continuous mapping theorem.

**Proof of Proposition 4.6(ii):** For brevity, we just analyze model 1.

$$\frac{1}{P^{1/2}} \sum_{t=R}^{T-1} (g(\widehat{u}_{1,t+1}^*) - g(\widehat{u}_{1,t+1})) = \frac{1}{P^{1/2}} \sum_{t=R}^{T-1} (g(u_{1,t+1}^*) - g(u_{1,t+1}))$$

$$+ \frac{1}{P^{1/2}} \sum_{t=R}^{T-1} \left( \nabla_{\theta_1} g(\bar{u}_{1,t+1}^*) (\hat{\theta}_{1,t}^* - \theta_1^\dagger) - \nabla_{\theta_1} g(\bar{u}_{1,t+1}) (\hat{\theta}_{1,t} - \theta_1^\dagger) \right), \quad (73)$$

where  $\bar{u}_{1,t+1}^* = y_{t+1} - \kappa_1(Z^{*,t}, \bar{\theta}_{1,t}^*)$ ,  $\bar{u}_{1,t+1} = y_{t+1} - \kappa_1(Z^t, \bar{\theta}_{1,t})$ ,  $\bar{\theta}_{1,t}^* \in (\hat{\theta}_{1,t}^*, \theta_1^\dagger)$  and  $\bar{\theta}_{1,t} \in (\hat{\theta}_{1,t}, \theta_1^\dagger)$ . As an almost straightforward consequence of Theorem 3.5 in Kunsch (1989), the first term on the RHS of (73) has the same limiting distribution as  $P^{-1/2} \sum_{t=R}^{T-1} (g(u_{1,t+1}) - E(g(u_{1,t+1})))$ . As for the second line in (73), it writes as:

$$\begin{aligned} & \frac{1}{P^{1/2}} \sum_{t=R}^{T-1} \nabla_{\theta_1} g(\bar{u}_{1,t+1}^*) (\hat{\theta}_{1,t}^* - \hat{\theta}_{1,t}) - \frac{1}{P^{1/2}} \sum_{t=R}^{T-1} (\nabla_{\theta_1} g(\bar{u}_{1,t+1}^*) - \nabla_{\theta_1} g(\bar{u}_{1,t+1})) (\hat{\theta}_{1,t} - \theta_1^\dagger) \\ &= \frac{1}{P^{1/2}} \sum_{t=R}^{T-1} \nabla_{\theta_1} g(\bar{u}_{1,t+1}^*) (\hat{\theta}_{1,t}^* - \hat{\theta}_{1,t}) + o_P^*(1), \quad \text{Pr}-P \\ &= \mu_1 B_1^\dagger \frac{1}{P^{1/2}} \sum_{t=R}^{T-1} (h_{1,t}^* - h_{1,t}) + o_P^*(1), \quad \text{Pr}-P, \end{aligned} \quad (74)$$

where  $h_{1,t+1}^* = \nabla_{\theta_1} q_1(y_{t+1}^*, Z^{*,t}, \theta_1^\dagger)$ ,  $h_{1,t+1} = \nabla_{\theta_1} q_1(y_{t+1}, Z^t, \theta_1^\dagger)$ . Also, the last line in (74) writes as:

$$\begin{aligned} & \mu_1 B_1^\dagger \left( a_{R,0}^2 \frac{1}{P^{1/2}} \sum_{t=1}^R (h_{1,t}^* - h_{1,t}) + \frac{1}{P^{1/2}} \sum_{i=1}^{P-1} a_{R,i} (h_{1,R+i}^* - \bar{h}_{1,P}) \right) \\ & - \mu_1 B_1^\dagger \frac{1}{P^{1/2}} \sum_{i=1}^{P-1} a_{R,i} (h_{1,R+i} - \bar{h}_{1,P}) + o_P^*(1), \quad \text{Pr}-P, \end{aligned} \quad (75)$$

where  $\bar{h}_{1,P}$  is the sample average of  $h_{1,t}$  computed over the last  $P$  observations. Given Lemma A3, by the same argument used in the proof of Theorem 1, the first line in (75) has the same limiting distribution as  $\frac{1}{P^{1/2}} \sum_{t=R}^{T-1} (\hat{\theta}_{1,t} - \theta_1^\dagger)$ , conditional on sample. Therefore we need to show that the correction term for model 1 (i.e. second and third, fourth line on the RHS of (50)) offsets the second line in (75), up to a  $o(1)$   $\text{Pr}-P$  term. Let  $h_{1,t+1}(\hat{\theta}_{1,T}) = \nabla_{\theta_1} q_1(y_{t+1}, Z^t, \hat{\theta}_{1,T})$  and  $\bar{h}_{1,P}(\hat{\theta}_{1,T})$  is the sample average of  $h_{1,t+1}(\hat{\theta}_{1,T})$ , over the last  $P$  observations. Now, by the uniform law of large numbers

$$\frac{1}{T} \sum_{t=s}^{T-1} \nabla_{\theta_1} g(\bar{u}_{1,t+1}^*) \left( \frac{1}{T} \sum_{t=s}^{T-1} \nabla_{\theta_1}^2 q_1(y_t^*, Z^{*,t-1}, \hat{\theta}_{1,T}) \right)^{-1} - \mu_1 B_1^\dagger = o_P^*(1), \quad \text{Pr}-P.$$

Also, by the same argument used in the proof of Theorem 1, it follows that,

$$\frac{1}{P^{1/2}} \sum_{i=1}^{P-1} a_{R,i} (h_{1,R+i} - \bar{h}_{1,P}) - \frac{1}{P^{1/2}} \sum_{i=1}^{P-1} a_{R,i} (h_{1,R+i}(\hat{\theta}_{1,T}) - \bar{h}_{1,P}(\hat{\theta}_{1,T})) = o(1), \quad \text{Pr}-P.$$
